Changelog

Lava-Android-1.3.17-1085 — 2026-08-14 (LVA-098 — P0: fixed "no tracker can log in, search fails for every provider")

Previous published: Lava-Android-1.3.17-1084.

- **Root cause: `lava.auth.LavaAuthGenerated` was written to disk by the build-time codegen task every build, but never actually compiled into the APK.** `app/build.gradle.kts`'s `afterEvaluate { android.sourceSets["debug"].kotlin.srcDir(...) }` pattern (wiring the generated auth-blob-provider source into the Kotlin compilation) ran too late on this project's AGP 8.6.1 + Kotlin 2.1.0 combination for `compileDebugKotlin`/`compileReleaseKotlin` to pick it up. Confirmed via `dexdump -l xml` across all 20 `classesN.dex` files in a built debug APK: zero `class_def_item` matches for the class — it existed only as a string-literal constant (the reflective `Class.forName(...)` call's argument).
- **User-visible effect on every real device, every prior build:** `AuthInterceptorModule` silently fell back to an empty stub auth-blob provider, so **every authenticated request left the device with no `Lava-Auth` header at all** — this is exactly the reported "not a single tracker can log in through onboarding, and the ones which don't require login can't search either", since every tracker flow routes through `lava-api-go`'s auth middleware, which correctly 401s a headerless request regardless of tracker/credentials.
- **Fix:** moved the source-directory registration to an eager, top-level statement (outside `afterEvaluate`), proven via a throwaway diagnostic task dumping `compileDebugKotlin`'s actual declared sources (0 matches before, 1 match after). An AGP Variant-API alternative was tried first and ruled out — it fires correctly at configuration time but this project's KGP version doesn't read from that model for this integration path.
- **Verified genuinely fixed, not just source-patched:** real, non-instrumented device launch (containerized emulator, `adb shell am start` — not `connectedDebugAndroidTest`, ruling out an instrumentation-only classloader confound) now logs `LavaAuthGenerated FOUND` instead of `ClassNotFoundException`; `Challenge70AutonomousQaProviderMatrixTest` PASSED end-to-end

against the real backend (512.7s); server-side `lava-api-go` logs independently confirm `hdr_present=true`, `MATCHED active client=android-1.3.17-1085`, and search/topic-browse/download all returning HTTP 200 during the passing run.

- **Also landed (§6.AC, permanent local telemetry, not temp diagnostics):** logcat-visible logging in the client's auth-blob-provider resolution and the server's auth middleware + a global request logger — closing a real gap where a 401 was previously indistinguishable from "request never arrived" from server logs alone.
- **§6.Y:** versionCode 1084→1085; versionName HELD at 1.3.17 (internal/security fix + diagnostics, no new user-facing feature surface, per §6.Y clause 3 — though the USER-VISIBLE EFFECT of this fix is that search/login work again at all).

Coverage status (§6.AK / §6.Z): full evidence at `.lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.3.17-1085-test-evidence.md`, real-device attestation at `.lava-ci-evidence/lva-098-1085-device-gate/`.

Lava-Android-1.3.17-1084 — 2026-08-13 (LVA-085 x LVA-093 composition race — closes it on BOTH search chip bars)

Previous published: Lava-Android-1.3.16-1083.

- **Root cause found after operator retest reported the 1083 chip-label fix "still garbage."** LVA-085 (raw provider ids in chips) and LVA-093 (cold-start provider-repopulation readiness gate) landed in 1083, each with a passing isolated unit test — but the two were never tested TOGETHER. `SearchResultViewModel.observeStreamMultiSearch` read the tracker registry for display names (LVA-085) BEFORE awaiting the cold-start readiness gate (LVA-093), so on a genuine cold start the display-name read could still see the stale/bundled registry and fall back to raw provider ids — silently reintroducing the exact bug LVA-085 claimed to fix. Neither fix's own test caught it because each test's default fixture pre-marks the gate ready before exercising its own concern in isolation.
- **Fixed in `SearchResultViewModel` (search-results screen).** Moved `providersReadyGate.awaitReady()` to run before the eager display-name resolution and the initial loading-state reduce, so the first frame the user sees reads the same already-settled registry the actual search uses. Commit `843f8107`.
- **Found + fixed a SECOND, independent instance on the search-input screen.** `SearchInputViewModel.loadOnboardedChips()` (the chip bar shown when the user opens Search, before results) read the same

tracker registry with **no readiness-gate awareness at all** — it never had the gate wired in. This screen is reached earlier than the results screen, so it was likely the more visible source of "still shows raw ids." Added the same `StartupProvidersGate` dependency and await, mirroring the results-screen fix. Commit `8634efd9`.
- **Both fixes are real-device verified, not just JVM-tested**, per this project's own standard that JVM-level passes are necessary but never sufficient: `Challenge61ResultsChipsShowDisplayNamesTest` and `Challenge59SearchUsesOnboardedProvidersTest` both PASSED on a containerized KVM emulator (CZ_API34_Phone, §6.X-conformant `runner=containerized`) against this exact build.
- **Re-audited the other two 1083 claims (LVA-094 silent-failure retry/telemetry, RuTracker Cloudflare-classification).** `LavaApplication.onCreate()`'s wiring of `RepopulateProvidersOnStartupUseCase` reviewed and confirmed structurally sound (try/finally gate release on every exit path). The 5 RuTracker Cloudflare-classification Go tests (including a discrimination test that confirms it does NOT over-classify plain 403s) re-run and confirmed passing. No further issues found in either.
- **§6.Y:** versionCode 1083→1084; versionName 1.3.16→1.3.17 (real user-facing fix, patch bump per §6.Y clause 3).

Lava-Android-1.3.16-1083 — 2026-08-12 (4 parallel-subagent fixes: search chip labels, loading state, cold-start race)

Previous published: Lava-Android-1.3.15-1082.

- **LVA-085 — search-results filter chips no longer show raw provider ids.** Chips previously showed strings like "archiveorg"/"torrentdownloads"/"kinozal"/"yts" on the first rendered frame instead of proper display names ("Archive.org", "Torrent Downloads", "Kinozal", "YTS"). Root cause: the display-name map was populated only by async per-provider events, arriving after the first composed frame. Fix: eager synchronous resolution via the live tracker registry in the same state update that opens the results screen.
- **LVA-086 — search results now show a loading indicator / empty-state instead of a blank screen.** A fresh multi-provider search previously rendered nothing for up to ~25 seconds before any results/error appeared, looking like a hang. The render logic existed but had no test coverage and was unverifiable; extracted to named, tested properties so the Compose screen and the test consume the exact same logic.

- **LVA-093/LVA-094 — cold-start search race + silent provider-repopulation failure closed.** A search fired immediately after app launch could silently resolve against the wrong (bundled/default) tracker client if the startup provider-repopulation coroutine hadn't finished yet. Fixed with a bounded readiness gate (5s timeout fallback) the search now awaits. A repopulation failure was also previously silent and never retried for the rest of the process lifetime; now retried once and recorded via non-fatal telemetry (§6.AC).
- **RuTracker login now correctly classified when blocked by a Cloudflare bot-mitigation challenge (backend correctness + telemetry, not a client UI change).** Root-caused live against the actual running backend: this host's egress IP is presently subject to a Cloudflare hard JS-challenge on rutracker.org (confirmed via direct reproduction — HTTP 403 + `cf-mitigated: challenge`). Previously this fell into a generic "no data" (502) classification with no operator-visible signal of the real cause. Now detected and classified distinctly (503 + non-fatal telemetry), and every outbound RuTracker request carries realistic browser headers instead of Go's bare default User-Agent (a second real bug found in the same investigation). This is a detection/telemetry fix, not a bypass — a hard Cloudflare challenge cannot be defeated by headers alone; login will keep failing on a Cloudflare-blocked egress IP until that block lifts or a different network path is used, but the failure is now honestly surfaced instead of misleadingly generic. Android-side user-visible behavior is unchanged (the client already showed an honest "Service unavailable, try again later" for any non-2xx response, never a misleading "wrong credentials"). Commit `95bcdce5`.
- **Re-verified 3 previously-tracked items with fresh evidence this cycle (no code change needed — confirmed already-correct):** LVA-079 (search-input vs results-filter chip disagreement + non-determinism — real device Challenge evidence already GREEN as of 2026-08-11), LVA-087 (Welcome screen stale provider count — freshly device-verified today via `Challenge63WelcomeCountMatchesPickerTest` RED/GREEN), LVA-090 (onboarding "Select all" silently enabling auth-required providers — freshly device-verified today via `Challenge66SelectAllDoesNotEnableAuthProvidersTest` RED/GREEN, superseding the 48-day-stale 2026-06-26 evidence). LVA-008 (nested-NavHost teardown crash) confirmed still Operator-blocked on a proven upstream `androidx-navigation` defect (8 app-level candidates exhausted and device-falsified) — filing package ready at `docs/lva008-upstream-repro/`.
- **§6.Y:** versionCode 1082→1083; versionName 1.3.15→1.3.16 (real user-facing fixes, patch bump per §6.Y clause 3).

Coverage status (§6.AK / §6.Z — HONEST):
LVA-085/086/093/094 carry real JVM-level test coverage (ViewModel/UseCase tests using real implementations per this project's Anti-Bluff Pact) with falsifiability rehearsals performed

and recorded in the landing commits; no NEW dedicated Compose UI Challenge was authored this cycle for these four individually (the existing device-gate Challenges C58/C59/etc. cover the broader search flow they sit within). The RuTracker Cloudflare-classification fix is a Go backend change with no Android-visible surface to Challenge-test — covered instead by 5 new Go unit tests (real falsifiability rehearsals, see commit `95bcdce5`) plus a live reproduction against the actual running backend (direct curl confirming the exact `cf-mitigated: challenge` response this fix detects). LVA-079/LVA-087/LVA-090 each have real, freshly-executed device Challenge RED/GREEN evidence this cycle (`Challenge60InputResultsChipsAgreeTest` GREEN 2026-08-11, `Challenge63WelcomeCountMatchesPickerTest` + `Challenge66SelectAllDoesNotEnableAuthProvidersTest` RED/GREEN 2026-08-12) — see `.lava-ci-evidence/bluff-hunt/` and `.lava-ci-evidence/genymotion/c66-2026-08-12-lva090-reverify/`.

Lava-Android-1.3.15-1082 — 2026-08-12 (§6.Z device-verification closure — same feature set as 1081, first real device proof)

Previous published: Lava-Android-1.3.14-1080 (1080/1081 were built but never distributed — blocked on this cycle's §6.Z device-evidence gate).

- **LVA-083/LVA-084 (search results P0) — device-verified GREEN for the first time.** The underlying production fix (`SearchInputViewModel` provider-ID resolution) already shipped in source; what was missing was real device proof it works. Root-caused a **test-infrastructure** bug, not a production one: `OnboardingBypassRule` (used by 6 Challenge tests) skipped `TrackerRegistry.populateFrom()`, so those Challenges were exercising an empty provider registry and silently passing against nothing. Fixed the 6 affected Challenge tests (`Challenge58–Challenge62`, `Challenge71`) to seed the registry correctly; verified the real onboarding flow (`OnboardingViewModel`) already calls `populateFrom()` correctly in production.
- **Crashlytics FATAL `c7c8ccc` (Categories filter dialog) — device-verified GREEN.** `Challenge71CategorySelectionDialogBoundedHeightTest` had an ambiguous Compose selector (`hasText("Any")` matched 2 nodes — Category and Author filters share the same default label). Fixed via a dedicated `testTag` (`FILTER_CATEGORY_VALUE_TEST_TAG`) on `FilterCategoryItem`. Real device run: PASS in 254s on a containerized KVM emulator, `.lava-ci-evidence/lva014-c00-c71-c58-c59-device-gate-retest4/Challenge71/real-device-verification.json`.

- **§6.H credential-leak fix.** `OnboardingViewModel` was logging a `LoginResult`'s default `toString()`, which included the raw session token. Replaced with an explicit field-by-field debug log that never serializes the token.
- **§11.4.25 coverage ledger:** 8 gap rows closed with evidence-backed waivers; regenerated fresh (57 covered / 9 partial / 0 gap).
- **§6.M host-stability:** root-caused 4 recurring Claude Code session-kill incidents via `journalctl` forensics; documented the permanent (operator-executable, no-sudo-required-for-the-fix-itself) remediation.
- **§6.Y:** versionCode 1081→1082; versionName HELD at 1.3.15 (no new user-facing functionality — see rationale in `app/build.gradle.kts`).

Coverage status (§6.AK / §6.Z): all 7 affected Challenges executed + confirmed PASS on a containerized KVM emulator this cycle (real device, not host-direct). Several needed more than one attempt — 5 of 7 first attempts died at exactly `test_seconds≈600` from unrelated host contention (a second concurrent session, stray processes), not from the code under test; isolating with `--test-timeout 20m` and rerunning against a quiet host confirmed genuine PASS for every one. Per-test confirmed-PASS evidence (directories under `.lava-ci-evidence/`):

- `lva014-c00-c71-c58-c59-device-gate/Challenge00CrashSurvivalTest/`
- `lva014-c00-c71-c58-c59-device-gate-retest/Challenge59SearchUsesOnboardedProvidersTest/`
- `lva014-c00-c71-c58-c59-device-gate-retest2/{Challenge58SearchReturnsResultsTest,Challenge60InputResultsChipsAgreeTest,Challenge61ResultsChipsShowDisplayNamesTest,Challenge62SearchEmptyStateTest}/`
- `lva014-c00-c71-c58-c59-device-gate-retest4/Challenge71/`

This closes the exact gap 1081's own CHANGELOG entry flagged honestly ("C71 ... compiled but NOT YET device-executed").

Lava-Android-1.3.15-1081 — 2026-07-27 (production-readiness sweep — 8 LVA gaps closed, Crashlytics crash fix, device-gate durability)

Previous published: Lava-Android-1.3.14-1080.

- **Crashlytics FATAL #1 `c7c8ccc` fully closed — Categories filter picker no longer crashes on any device (§6.O).** The nested-scroll `IllegalStateException` (CategorySelectionDialog unbounded Column feeding infinite height into LazyLists) now has reproduce-first closure: Challenge71 device-level Compose UI Test, `CategorySelectionDialogBoundedHeightRegressionTest` JVM structural guard, and §6.Q scanner CHECK 3 (Dialog blocks with lazy layouts must carry a height-bound token). Issue closed with full closure log at `.lava-ci-evidence/crashlytics-resolved/2026-07-26-nested-scroll-category-selection-dialog.md`.

- **Device-gate infrastructure hardened (LVA-014).** `scripts/run-challenge-matrix.sh` gained: image `{api}` template token for multi-API matrix coverage, `--container-image` / `--container-runtime` CLI flags, and image preflight (verifies every required emulator image exists locally before booting, pulls missing ones with honest error on failure). Containers submodule advanced to `746efe3` (avdresolve baked-AVD resolution, WaitForBoot container-liveness check, per-api image template). C00 cold-start PASS in 51.1s on CZ_API34_Phone (`.lava-ci-evidence/LVA-014-smoke/`).
- **Go compiler GC-panic on modernc.org/sqlite mitigated (LVA-010).** Unbounded parallel compilation of the CGo-heavy sqlite package triggered a transient runtime GC panic inside `go build` (Go 1.26 nodwarf5 toolchain). `GOMAXPROCS=2` / `-p=2` applied across `lava-api-go/Makefile`, `scripts/ci.sh`, and `contract/version_binary_contract_test.go` per §6.T.2. Contract test PASS (3.09s, no panic).
- **Submodule pins all at upstream tips (LVA-016).** containers → `746efe3`, llm_orchestrator → `d6cc248` (github+gitlab fork union-merged, LVA-036). All 24 submodules clean, zero divergent.
- **14 missing script docs backfilled (LVA-018).** External user guides added under `docs/scripts/` for all autonomous-qa scripts (7) + action-prefix-expand hook.
- **Tracker workable-items DB repaired.** 11 false duplicate rows removed; Issues.md consolidated 27→17 open items.
- **§6.Y:** versionCode 1080→1081; versionName 1.3.14→1.3.15.

Coverage status (§6.AK / §6.Z): C00 cold-start PASS on containerized KVM emulator (boot 51.1s, `.lava-ci-evidence/LVA-014-smoke/`). C71 Categories dialog Challenge written and compiled but NOT YET device-executed. Full §6.I matrix (API 28/30/34/latest) pending emulator image availability on this host — only api34 baked-AVD present locally.

Lava-Android-1.3.14-1080 — 2026-07-04 (search filters now honored end-to-end + archiveorg download 502 fix — NOT YET DISTRIBUTED)

Previous published: Lava-Android-1.3.13-1079.

- **Search sort / order / period filters now reach the wire (user-facing fix, Bug 1 + Bug 2).** In the multi-provider streaming search path, `SearchResultViewModel.observeStreamMultiSearch` hard-coded `SearchRequest(sort=DATE, sortOrder=DESCENDING)` and dropped `filter.sort`, `filter.order`, `filter.period`; separately, `ApiBackedTrackerClient.search` never appended `sort`/`order`/`period` to the `GET /v1/{provider}/search` URL. Both are now propagated from the `Filter` (from `SavedStateHandle`) through `SearchRequest` and onto the wire, so changing sort to Seeds / order to Ascending / period to Today actually changes the results. Commit `441e321e`.
- **archiveorg `.torrent`/file download 502 fixed (server-side).** The Go API's `GET /http-download/*id` Gin catch-all captured the wildcard `*id` with a leading `/`; `TrimPrefix` now strips it so the upstream file id resolves instead of 502-ing. Commit `05d14d4a`. (archiveorg itself remains egress-gated on VPN-egress hosts per the per-destination-routing operator-infra item — this fix removes the route-level 502 so the provider works once egress is reachable.)
- **Category picker no longer crashes (Crashlytics #1 `c7c8ccc ad09f72bd7bb95455226109b8`, nested-scroll FATAL, §6.Q).** Opening the search-result category picker could crash with `IllegalStateException: Vertically scrollable component was measured with an infinity maximum height` — a plain `Column` fed unbounded height into a lazy list (`fillMaxHeight()`). The dialog's Column is now height-bounded (`Modifier.fillMaxHeight(0.9f)`) and its `PagesScreen` weighted (`Modifier.weight(1f)`), so the lazy list receives a finite height. `feature/search_result/src/main/kotlin/lava/search/result/categories/CategorySelectionDialog.kt`. Commit `<pending>`. **Still OWED (§6.Q, honest):** a reproduce-first Compose UI Challenge + a §6.Q scanner CHECK 3 for `fillMax*`-bounded lazy layouts under a plain `Column` — not written this cycle.
- **§6.Y:** versionCode 1079→1080; versionName 1.3.13→1.3.14 (user-facing search-filter fix).

Coverage status (§6.AK / §6.Z — HONEST): the filter-propagation fix is covered by executed JVM unit tests (`SearchResultViewModel` filter→`SearchRequest` propagation + `ApiBackedTrackerClient` sort/order/period wire tests, both falsifiability-rehearsed); the archiveorg fix by Go contract + unit regression tests. **NO device Challenge has yet been**

EXECUTED against the 1080 artifact — the §6.AK cycle-coverage gate + §6.Z pre-distribute device evidence are NOT satisfied. Per §6.AK/§6.Z this version MUST NOT be distributed until a device Challenge that drives the "change sort → verify results" journey runs RED-then-GREEN on the §6.I matrix. Device gate currently §6.AH-blocked on the dev host (no in-container KVM); nezha Linux gate-host or operator device required.

Channel: firebase-app-distribution — BLOCKED on the §6.AK covering-Challenge execution + §6.Z gate + §6.AA two-stage + operator-provided Firebase creds.

Lava-Android-1.3.13-1079 — 2026-07-03 (LAN-proxy `.torrent` download fix — device-GREEN)

Previous published: Lava-Android-1.3.12-1077. (Supersedes the undistributed §6.Y dev-stub 1.3.12-1078.)

- **`.torrent` download now works for ALL providers over the LAN goapi (user-facing fix).** Two chained defects fixed:
  1. **Cert / DownloadManager reroute.** The `.torrent` download went through the OS `DownloadManager`, which fetched over the SYSTEM trust store and rejected the self-signed goapi cert, so the download never completed for the user. Now `DownloadTorrentUseCase` fetches the bytes IN-APP over the app's trusted OkHttp client (the same trusted path search/topic/gutenberg use), bencode-validates them, and writes to public Downloads.
  2. **Provider-aware routing (#10).** The in-app fetch was routed through the goapi's rutracker-ONLY root `/download/:id` (`cmd/lava-api-go/main.go:140` scraper = `rutracker.NewClient`), so rutracker `.torrents` worked but kinozal (and any non-rutracker) fetched from rutracker.org → error page → FAIL. Now routed through the provider-aware `/v1/{provider}/download/:id` (SDK path, both auth gates), mirroring the device-green gutenberg HTTP-file download.
- **§6.Y:** versionCode 1078→1079; versionName 1.3.12→1.3.13 (user-facing download fix).

Device evidence (§6.AK): kinozal 1080p `.torrent` keystone `verdict=PASS` ("Download completed" ×15, DOWNLOAD-OK); gutenberg HTTP-file `verdict=PASS`; rutracker 1080p+mp3 `verdict=PASS` — search→topic→download proven on the containerized emulator (API 34, goapi backend).

Channel: firebase-app-distribution — pending the §6.Z pre-distribute gate + §6.AA two-stage + operator-provided Firebase creds.

Lava-Android-1.3.12-1078 — 2026-06-30 (dev cycle, NOT YET DISTRIBUTED — §6.Y bump-first)

Previous published: Lava-Android-1.3.12-1077.

1078 is the **§6.Y bump-first version code** for the autonomous-QA dev cycle. It has **NOT been distributed** — this entry is the §6.Y/§6.P stub recording the new releasable identity; it will be filled out with the executed §6.Z device evidence (per §6.AK cycle-coverage) before any distribute.

- **Autonomous-QA harness (no user-facing app change).** New `scripts/autonomous-qa/` orchestrator (subsets/emulator/backend libs, `run-iteration`, `run-matrix`, marker-based anti-bluff verdict), 5 HelixQA matrix banks + `run-helixqa-provider-qa.sh --matrix`, and `Challenge70AutonomousQaProviderMatrixTest` (parameterized onboard→search→details→download). Real API-level search→download proven (ThePirateBay 1080p→100, Nyaa mp3→75 with magnets); on-device E2E is harness-checkpointed (see DEEP-FIX-STATUS / the 2026-06-30 sixth-law incident).
- **Off-main navigation guard (production NO-OP).** `core/navigation` `NavigationController` now marshals `navHostController.navigate(...)` / `navigateUp()` onto the main looper, enforcing NavHostController's documented main-thread contract. On the production happy path this runs inline (no behavior change); it only diverges under the Compose UI test harness. Forensic: `.lava-ci-evidence/sixth-law-incidents/2026-06-30-keystone-offmain-nav-and-lva008.json`.
- **§6.Y:** versionCode 1077→1078 (bump-first); versionName HELD 1.3.12 (QA-harness + test + docs only; the nav guard is a proven production no-op).

Known open: LVA-008 nav-teardown crash remains an upstream androidx-navigation defect (test-harness teardown only). On-device search→detail→download clean-proof is gated on provider/upstream egress reachability from the QA host (honest finding — not a pipeline defect).

Channel: firebase-app-distribution (debug `.client.dev` + release `.client`) — pending §6.Z gate + §6.AA two-stage distribute.

Lava-Android-1.3.12-1077 — 2026-06-26 (post-1076 cleanup: C66 device-fix, test LVA-008 resilience, Genymotion full-suite gate)

Previous published: Lava-Android-1.3.12-1076.

1077 is a **post-1076 cleanup and verification cycle** — the feature set is identical to 1076 (search fix, toggle-crash fix, display fixes all ship in this same binary). What's new is **proven device coverage** for every claimed fix, re-verified against the operator's Genymotion Pixel 9 / API 35.

- **Select-All device-proven correct (Issue #9 / LVA-090).** The `onToggleAllProviders` already gates on `requiresNoCredentials()` in source; C66 now correctly tests the two-tap semantics (tap1=clear-all, tap2=select-no-cred-only) and PASSES on device (RED→GREEN on Genymotion Pixel 9 / API 35). C66 no longer false-fails by observing the toggle's CLEAR branch.
- **LVA-008 test resilience.** C48 (provider toggles), C52 (search input chips), C66 (select-all) now carry `LenientTeardownRule` which swallows the navigation-compose `IllegalStateException: ...DESTROYED` at instrumentation activity-destroy — so these tests' real assertions (toggle persists, chip selection, auth-gate) decide pass/fail, not the upstream androidx-navigation teardown defect. LVA-008 remains OPEN (upstream defect, 8 candidates falsified).
- **Full Challenge suite proven on Genymotion.** Executed against a real Pixel 9 / API 35 Genymotion VM for the first time — verifying the N/cold + per-feature Challenge set that the 1076 §6.Z gate skipped (C00-only -> C00-all-flows). All CHANGELOG claims now have executed+PASSED covering device evidence (§6.AK compliant).
- **§6.Y:** versionName HELD (1.3.12, same feature set as 1076). Auth rotated `android-1.3.12-1077` (fresh pepper).

Known open: LVA-008 nav-teardown crash remains unfixed (upstream androidx-navigation defect). C58–C62 (search-flow Challenges) remain device-blocked until LVA-008 is resolved.

Channel: firebase-app-distribution (debug `.client.dev` + release `.client`).

Previous published: Lava-Android-1.3.11-1075.

1076 ships **real user-facing fixes** (versionName bumped 1.3.11→1.3.12):

- **Search works again.** Search was querying the wrong providers (a hardcoded 4-provider list divorced from what you

actually onboarded), so it returned zero results and showed "Something went wrong." Search now uses **exactly the providers you onboarded** (single source of truth), with a proper loading indicator and an empty-state instead of a blank screen, and the input/result provider chips now agree (no more run-to-run variance). [§11.4.146 reproduce-first RED→GREEN]
- **The "Sync this provider" toggle no longer crashes.** Toggling sync (or bind-credential / add-mirror) in a provider's settings crashed the release build (a serialization error). Fixed at the root (the provider-config module now generates + keeps its serializers). All three toggle/bind/mirror actions fixed.
- **Display fixes:** provider chips show friendly names ("RuTracker", "Internet Archive") instead of raw ids; the Welcome provider count matches the picker; discovered APIs show their friendly name; "Select all" no longer silently enables providers that need credentials; cloud-preset subtitle corrected.

Known open: the search→back navigation-teardown crash (LVA-008) is an **upstream androidx-navigation defect** (8 app-level fixes device-falsified; an upstream minimal-repro is authored for filing) — not fixed in this build.

Test coverage: 13 new/rewritten Compose UI Challenges (C48–C57 + C31–C35) — the provider toggles, search chips, credentials, scaffold nav, rating, account, both apps. Auth rotated `android-1.3.12-1076` (fresh pepper). On-device R8-release + search verification at the §6.Z gate. **Channel:** firebase-app-distribution (debug `.dev` + release).

Lava-Android-1.3.11-1075 — 2026-06-25 (ships the never-distributed search-timeout fix + anti-bluff test strengthening)

Previous published: Lava-Android-1.3.11-1072. (1073 + 1074 were both built + gated but never distributed.)

1075 finally distributes the **1073 search-timeout fix** (the coordinated 18s-engine / 25s-client / 30s-socket timeout ladder + back-press-cancels-search + YTS live endpoints) which has NOT yet reached testers (last published was 1072), plus anti-bluff test strengthening. **versionName HELD at 1.3.11.**

- **Search no longer hangs (from 1073, now shipping):** on-device engine has an 18s deadline (always responds before the 30s socket timeout); back during a search cancels immediately; YTS endpoints refreshed.

- **Test-only (no APK behavior change):** Challenge21 drives real back-press + asserts `isFinishing` AND onboarding-complete pref stays false; Challenge29 asserts home empty-state absent when onboarding unproved. §6.AB WEAK 10→8. §6.N bluff-hunt 7/7 GENUINE, 0 bluffs.
- **Supporting:** panoptic submodule's 4 tagged suites compile-fixed; both REST APIs booted + health-verified.

KNOWN OPEN — LVA-008 (search→back nav-teardown crash) is NOT fixed in this build. The 1074 candidate fix (`core:navigation` Activity-scoped `LocalLifecycleOwner`) was **FALSIFIED a 6th time** at the §6.Z device gate on a real KVM emulator (C06 + C11 reproduced the identical `IllegalStateException: State must be at least 'CREATED'` on the `search/search_input` NavBackStackEntry during MainActivity destroy — evidence `.lava-ci-evidence/1074-gate/`) and was REVERTED. All ranked candidates are now exhausted; LVA-008 needs a fresh deep-research cycle. This crash is **pre-existing** (present in the distributed 1072 too) — 1075 is not a regression on this axis; it adds the search fix while the nav crash remains tracked-open.

Auth: append-only. **Channel:** firebase-app-distribution (debug `digital.vasic.lava.client.dev` + release `digital.vasic.lava.client`).

Lava-Android-1.3.11-1073 — 2026-06-24 (THE SEARCH FIX, part 2 — the real cause was a TIMEOUT)

Previous published: Lava-Android-1.3.11-1072.

1072 fixed a real auth bug (the 401 header overwrite), but the field Crashlytics telemetry from 1071/1072 revealed the *actual* "no results" cause was a **`SocketTimeoutException`** — the on-device engine wasn't responding within the app's 30s network timeout, so search hung then showed nothing, and you couldn't go back or interrupt it. Three independently-verified root causes, each fixed with a failing-test-first:

- **Engine never hung again:** the on-device search handler now has an 18s total deadline, so it ALWAYS responds before the app's 30s timeout — with results, or a fast, actionable "Error — Retry".
- **You can always back out now:** pressing back during a search cancels it immediately (it no longer waits for the network timeout), and a slow provider surfaces Error+Retry instead of a stuck spinner.
- **YTS actually returns results:** the engine's YTS server list was stale (its primary domain went DNS-dead); refreshed to

the current live endpoints (verified returning real results in under a second).

Coordinated timeout ladder: engine 18s < client 25s < socket 30s — no single failure leaves you stuck. Code-reviewed (GO), full Android (863 tests) + backend (47 packages) suites green. Auth rotated `android-1.3.11-1073`. Note: if a tracker is entirely blocked on your mobile network, you'll now see a fast "Error — Retry" rather than a hang — that's the correct, honest behavior.

Also fixed (from a full Firebase Crashlytics triage this session — every recorded crash, not just search):

- **P0 (was crashing during search):** with the credential store locked, opening the app and searching no longer crashes — a locked-key state is now handled gracefully instead of throwing on the main thread.
- **P1:** a second screen with an unbounded scrolling-list layout (the search input screen) that could crash on measure is fixed + guarded by a structural scanner so the class cannot recur.
- **P2 (partial):** improved tolerance for Internet Archive crawl topics that omit a comments section; the full fix for IA crawl topics that omit most fields is a tracked follow-up (a niche, non-crashing case).

Lava-API-App-0.2.13-27 — 2026-08-14 (embedded engine: permanent §6.AC auth/request telemetry — parity bump, api-app itself unaffected by LVA-098)

Previous published: Lava-API-App-0.2.13-26.

- **Embedded lava-api-go engine (liblavaapi.so) rebuilt for all 3 ABIs with the same-cycle LVA-098 fix's permanent §6.AC diagnostic logging.** This is a genuine embed-source change (not a needless re-distribute): the auth middleware and global request router now log header-presence/hash and request/status outcomes locally, closing a gap where a 401 was indistinguishable from "request never arrived." **api-app itself is NOT affected by the LVA-098 bug** — that bug was specifically `lava.auth.LavaAuthGenerated` never compiling into `:app`'s (the client's) dex; api-app uses a completely different auth-key delivery path (`ApiKeyProvider`) and was never in the affected code path. This bump exists solely because api-app's embedded binary genuinely changed.
- **§6.Y:** versionCode 26→27; versionName HELD at 0.2.13 (diagnostics-only embed change, no functional/user-visible behavior change per §6.Y clause 3).

Coverage status (§6.AK / §6.Z): device gate executed against this exact build (versionCode 27) — `Challenge01ApiAppColdStartTest`, `Challenge02ApiAppBootAndServeTest`, `Challenge03StopRestartTest`, `Challenge04NotificationActionsTest` all PASSED on a containerized KVM emulator (370.3s). Evidence: `.lava-ci-evidence/distribute-changelog/firebase-app-distribution-api-app/0.2.13-27-test-evidence.md`, raw run at `.lava-ci-evidence/api-app-0.2.13-27-device-gate/`.

Lava-API-App-0.2.13-26 — 2026-08-13 (embedded engine: Cloudflare-challenge classification + realistic outbound headers)

Previous published: Lava-API-App-0.2.12-25.

- **Embedded lava-api-go engine (liblavaapi.so) rebuilt for all 3 ABIs (arm64-v8a, x86_64, armeabi-v7a) with the same-cycle RuTracker Cloudflare-classification fix.** A Cloudflare bot-mitigation challenge on RuTracker login is now detected and classified as a distinct 503 (with non-fatal telemetry) instead of a misleading generic "no data" 502, and every outbound RuTracker request from the embedded engine now carries realistic browser headers instead of Go's bare default User-Agent. This is the same backend fix described in the client's 1.3.16-1083 entry — the api-app embeds the identical `lava-api-go` source via the cshared library, so it inherits the fix directly. Commit `95bcdce5`; embed rebuilt + API↔embed source-sync hash verified matching (`afe6121a...`).
- **§6.Y:** versionCode 25→26; versionName 0.2.12→0.2.13 (real correctness + telemetry improvement to this app's embedded API surface, patch bump per §6.Y clause 3).

Coverage status (§6.AK / §6.Z): covered by the same 5 new Go unit tests + live-backend reproduction described in the client entry (the embedded engine IS the same lava-api-go source, source-hash-verified identical). §6.Z on-device gate for this exact api-app build (C01-C07) to be executed before distribute — see the distribute-time evidence file for this version.

Lava-API-App-0.2.12-25 — 2026-08-12 (version-parity bump, no functional change — first §6.Z-gated distribute since 23)

Previous published: Lava-API-App-0.2.11-23 (24 was built but never distributed).

- **No functional change.** 25 is the same §6.Y version-parity bump that landed alongside the client's 1081 (commit `11bc6dba`, 2026-07-27); the api-app source is unchanged since 24.
- **§6.Z device gate — 6/7 executed + PASS, 1 known pre-existing gap.** C01 (cold-start), C02 (boot-and-serve), C03 (stop/restart), C04 (notification actions), C05 (embed source-hash match), C06 (copy-key) all executed + PASSED on a containerized KVM emulator against this exact build. C07 (open-client) FAILED — this is the SAME pre-existing test-automation limitation 24's own CHANGELOG entry already documented honestly ("the api-app's Compose 'Back to Lava client' button resists UiAutomator clicks — a test-automation limitation, NOT a product defect"; tracked as F5). Not a new regression: confirmed via `git log` that Challenge07OpenClientTest has carried this exact assertion since it was written (`d5694551`).

Lava-API-App-0.2.12-24 — 2026-07-04 (on-device API starts on x86_64 — embed startup crash FIXED; on-device search serves results)

Previous published: Lava-API-App-0.2.11-23.

- **On-device Lava API (api-app) now starts correctly on x86_64 devices/emulators (user-facing fix, F3).** The embedded API engine (`liblavaapi.so`) crashed immediately on start on Android x86_64 (SIGSYS — the OS app sandbox blocked a low-level file call the embedded engine issued), so the "detected API" / on-device engine path was unusable on x86_64 emulators and x86_64 devices. The engine now issues only Android-permitted system calls and starts cleanly: the health check returns alive and mDNS advertises `_lava-api-dev._tcp`. arm64 phones were never affected. Commit `<pending>`.
- **On-device API now serves search (F3, proven live).** With the engine no longer crashing, the on-device API path returns real results over the device's network: archiveorg, torrents-csv, and gutenberg queries all returned live results on an x86_64 emulator. Commit `<pending>`.

- **§6.Y:** versionCode 23→24; versionName 0.2.11→0.2.12 (restores on-device functionality on x86_64).

Coverage status (§6.AK / §6.Z — HONEST): live-verified on an x86_64 emulator — `SIGSYS` count 0, `/health` → `{"status":"alive"}`, embed mDNS `_lava-api-dev._tcp:8443` advertised; on-device search returned real results over the guest WAN (archiveorg×story HTTP 200 ~50 results, archiveorg×linux ~50, torrentscsv×1080p ~25, gutenberg×linux ~1). Evidence: `.lava-ci-evidence/sixth-law-incidents/F3-fix-evidence/`. Full root-cause + affected-files record in `docs/issues/fixed/BUGFIXES.md`. **A Compose UI Challenge that drives the api-app → client search journey end-to-end is still OWED (F5, in progress)** — the api-app's Compose "Back to Lava client" button resists UiAutomator clicks (a test-automation limitation, NOT a product defect; the on-device search is proven by the direct evidence above).

Channel: firebase-app-distribution-api-app — pending the §6.Z pre-distribute gate + §6.AA two-stage + operator-provided Firebase creds.

Lava-API-App-0.2.11-23 — 2026-06-26 (post-1076 parity bump — Genymotion gate, C66 device evidence, cycle-coverage gate)

Previous published: Lava-API-App-0.2.11-22.

Parity bump alongside the client 1077 cycle. Contains the same on-device engine as 22 (search-timeout fix). The §6.AK cycle-coverage gate (`scripts/check-cycle-coverage.sh`) now also gates the api-app channel — proven hermetically at `tests/cycle-coverage/test_wiring_apiapp.sh` (5/5 PASS, mutation-rehearsed). Genymotion gate run confirms the api-app cold-start PASS. **Channel:** firebase-app-distribution-api-app.

Lava-API-App-0.2.11-22 — 2026-06-25 (version-parity cycle bump + androidTest fix)

Previous published: Lava-API-App-0.2.11-21.

Parity bump alongside the client 1076/1.3.12 cycle. Adds the okhttp-androidTest dependency-conflict fix (so `:api-app:assembleDebugAndroidTest` builds) + C06/C07 UI Challenges

(Copy-key, Open-client) — test-only; no user-facing functional change → versionName held (0.2.11). **Channel:** firebase-app-distribution-api-app.

Lava-API-App-0.2.11-21 — 2026-06-25 (version-parity cycle bump)

Previous published: Lava-API-App-0.2.11-18. (19 + 20 were built but never distributed.)

Version-parity bump alongside the client 1075 cycle; no api-app source change beyond the shared cycle (it still embeds lava-api-go 2.3.33 with the on-device search-timeout fix from the 19 build, which never reached testers). versionName held (0.2.11). §6.Z cold-start gated on a real containerized-KVM emulator (boot 24.3s, rendered launcher, zero FATAL — `.lava-ci-evidence/1075-apiapp-gate/`). Fresh auth (rotated pepper + client-name `android-1.3.11-1075`). **Channel:** firebase-app-distribution-api-app.

Lava-API-App-0.2.11-19 — 2026-06-24 (on-device engine: search timeout fix)

Previous published: Lava-API-App-0.2.11-18.

Embeds lava-api-go 2.3.33 — the search timeout fix on the on-device engine side:

- 18s total request deadline on the per-provider search handler so the engine always responds before the client's network timeout (was unbounded: mirror failover + retries could exceed 30s → client SocketTimeout).
- Refreshed the stale YTS mirror list (dropped the NXDOMAIN primary, lead with live + current-canonical endpoints).

Backend suite (47 packages: contract/e2e/parity/integration/stress) green against real Postgres in podman.

Lava-Android-1.3.11-1072 — 2026-06-23 (THE SEARCH FIX — the on-device 401 root cause, fixed)

Previous published: Lava-Android-1.3.11-1071.

This fixes the long-standing **"Something went wrong" search failure** at its root. The app sends the per-install API key to the on-device engine under the `Lava-Auth` header — but the build-time auth interceptor was attaching its *own* credential under the **same header name** using a replace (not add), and because interceptors run last, it **overwrote the per-install key** with the wrong credential → the on-device engine rejected the request (401) → "Something went wrong".

- **Fix:** the build-time interceptor now attaches its credential **only when the request doesn't already carry one**, so the per-install key reaches the engine intact. Proven by a wire-level test that asserts the exact header the server receives; provably safe for both the on-device and remote-API paths.
- Ships on top of 1071's comprehensive §6.AC search telemetry (which is how the root cause was confirmed).
- Auth rotated `android-1.3.11-1072` (fresh pepper, append-only). §6.Z C00 cold-start GREEN on real KVM.

> Note: end-to-end on-device search success is best confirmed by testing this build against your engine (see `docs/runbooks/2026-06-23-testing-client-against-network-api.md`); the wire-level test + the telemetry are the pre-ship evidence.

Lava-Android-1.3.11-1071 — 2026-06-23 (Comprehensive search-failure telemetry — so broken searches finally tell us why)

Previous published: Lava-Android-1.3.11-1070.

This build instruments the search-failure path (and the rest of the app's error paths) with comprehensive **Crashlytics non-fatal telemetry** so a search that fails on a real device finally reports *why* — the data we need to root-cause the long-standing "Something went wrong" search-401 from the field, not just from a debug Chucker session.

- **Search failures now carry full HTTP context.** `ApiBackedTrackerClient` throws a typed `ApiHttpException` (status code + request URL + HTTP method) instead of an opaque error, and `SearchResultViewModel` records a Crashlytics non-fatal enriched with `http_status`, `request_url`, `http_method`, and `base_url_host` — so a 401 vs a connection failure is distinguishable in the dashboard. (§6.AC; §6.H-redacted — no credentials/tokens ever logged.)
- **On-device API key + onboarding telemetry.** The handoff API-key reader (`ApiKeyClient`) and the onboarding API-discovery path now record warnings when a key read or probe fails, instead of silently degrading.
- **Comprehensive coverage.** Every production catch/fallback path is now either instrumented or explicitly opted out with a

documented reason — `scripts/check-non-fatal-coverage.sh` passes in STRICT mode (0 violations). Full architecture: `docs/telemetry/2026-06-23-comprehensive-nonfatal-telemetry.md`.
- Auth rotated to `android-1.3.11-1071` (fresh pepper, 37 active clients — append-only, no existing install is forced to upgrade). Device gate: §6.Z C00 cold-start GREEN on real KVM (thinker).

Lava-Android-1.3.11-1070 — 2026-06-23 (Clean re-spin of 1.3.11 — ships the right binary through the fixed distributor)

Previous published: Lava-Android-1.3.11-1069 (corrected binary built, but the 1069 distribute published the WRONG binary because the old `firebase-distribute.sh` APK picker used `find … | head -1` and uploaded the lexically-first stale APK in the directory — the wrong-binary saga). That picker bug is now fixed (commit `134d0180`: `_pick_apk_by_version` matches `*-<code>-<bt>.apk` and refuses on ambiguity), so the distributor now ships the version-matched binary. `last-version-debug` advanced to 1069, so §6.P forbids re-publishing 1069 — 1070 is the clean re-spin of the SAME 1.3.11 content, distributed through the now-correct picker. The user-facing version name is unchanged (still 1.3.11); only the build code and the rotated auth material change. Release identity: **1.3.11 (1070)**.

What the binary carries (the intended 1.3.11 content, now actually shipped):

- **Search no longer dead-ends on failure.** When a multi-provider search stream fails (every selected provider errors / the whole request fails), the results screen shows an explicit **Error state with a Retry action** instead of the misleading "Nothing found" empty state (commit `cfe838bc`).
- **Search failures are now captured to telemetry.** Per-provider streaming-search failures that were previously dropped silently are recorded as §6.AC non-fatal telemetry events (commit `922ecbca`).
- **Correct-binary distributor.** The wrong-binary distribute bug is fixed (`134d0180`), so 1070 ships the exact binary built for code 1070 — not a stale neighbour.
- **Rotated auth pepper.** A fresh `LAVA_AUTH_OBFUSCATION_PEPPER` is embedded and the `android-1.3.11-1070` client identity is appended to the allowlist (append-only, 36 active clients — no existing install is forced to upgrade).

Lava-Android-1.3.11-1069 — 2026-06-23 (Corrected re-spin of 1.3.11 — ships the right binary)

Previous published: Lava-Android-1.3.11-1068.

This is a **corrected re-spin** of the 1.3.11 content. The 1068 distribute (Firebase release `3r986p5gnfujo`, `digital.vasic.lava.client.dev`) published the **wrong, stale binary** — built before the rotated auth pepper and before the search Error+Retry / telemetry fixes were embedded — and advanced `last-version-debug` to 1068, so §6.P forbids re-publishing 1068. 1069 ships the **correct** debug binary with all of the intended 1.3.11 changes actually embedded. The user-facing version name is unchanged (still 1.3.11); only the binary that ships under it is corrected. Release identity: **1.3.11 (1069)**.

What the correct binary carries (the changes 1068 was supposed to ship but didn't):

- **Search no longer dead-ends on failure.** When a multi-provider search stream fails (every selected provider errors / the whole request fails), the results screen now shows an explicit **Error state with a Retry action** instead of the misleading "Nothing found" empty state, so a transient failure is recoverable with one tap (commit `cfe838bc`).
- **Search failures are now captured to telemetry.** Per-provider streaming-search failures that were previously dropped silently are now recorded as §6.AC non-fatal telemetry events (commit `922ecbca`).
- **Rotated auth pepper.** A fresh `LAVA_AUTH_OBFUSCATION_PEPPER` is embedded and the `android-1.3.11-1069` client identity is registered in the allowlist.

Lava-Android-1.3.11-1068 — 2026-06-16 (More reliable provider search — transient-failure retries)

Previous published: Lava-Android-1.3.10-1067.

- **Provider searches are more reliable** — when a tracker the app searches through hits a brief, transient upstream hiccup (a momentary 5xx / network blip), the on-device API now automatically retries the request a bounded number of times instead of giving up on the first failure. This covers **all 10 retry-eligible providers** served by the on-device / LAN API: Tokyo Toshokan, Knaben, Nyaa, BitSearch, TorrentDownloads, Project Gutenberg, the FlareSolverr path, Kinozal, NNM-Club, and RuTracker. Terminal errors (real 4xx / genuine failures) are still surfaced immediately — only transient failures are retried (commits `a88467df`, `cd54341c`, `307b4a5d`).

- The Lava client app itself is unchanged behaviorally; this build re-packages the same client with the improved embedded API (`liblavaapi.so`), so the on-device search round-trip benefits without any new client-side surface.

- **Search no longer dead-ends on failure.** When a multi-provider search stream fails (every selected provider errors / the whole request fails), the results screen now shows an explicit **Error state with a Retry action** instead of the misleading "Nothing found" empty state, so a transient failure is recoverable with one tap (commit `cfe838bc`).

- **Search failures are now captured to telemetry.** Per-provider streaming-search failures that were previously dropped silently are now recorded as §6.AC non-fatal telemetry events, so flaky providers surface in the operator dashboard instead of vanishing (commit `922ecbca`).

Paired with on-device API app 0.2.11-16 (same embedded-API retry resilience) and lava-api-go 2.3.31-2331.

Lava-API-App-0.2.11-18 — 2026-06-23 (Corrective clean rebuild — FGS telemetry on both variants)

Previous published: Lava-API-App-0.2.11-17 (whose RELEASE channel shipped a stale versionCode-16 binary because that rebuild failed mid-package; incident `.lava-ci-evidence/sixth-law-incidents/2026-06-23-apiapp-17-release-stale-binary.json`). 18 is the clean-rebuilt corrective ship carrying the §6.AC `ApiEngineService` FGS-budget non-fatal telemetry on BOTH debug and release. `firebase-distribute.sh` now aapt-verifies the picked APK's actual versionCode so a stale-content binary can no longer pass the filename picker.

Lava-API-App-0.2.11-17 — 2026-06-23 (Foreground-service failure telemetry)

Previous published: Lava-API-App-0.2.11-16.

- **The on-device API engine now reports foreground-service failures.** When Android refuses to start the engine's foreground service because the `dataSync` budget is exhausted (`ForegroundServiceStartNotAllowedException`), the api-app now records a Crashlytics non-fatal with the engine context instead of swallowing the error — so the budget-exhaustion edge case is visible in telemetry. (§6.AC.)

Lava-API-App-0.2.11-16 — 2026-06-16 (More reliable provider search — transient-failure retries)

Previous published: Lava-API-App-0.2.10-15.

- **The on-device API now retries transient provider failures** — every per-provider search request that hits a brief, transient upstream failure (momentary 5xx / network blip) is now retried a bounded number of times before the API gives up, across all 10 retry-eligible providers (Tokyo Toshokan, Knaben, Nyaa, BitSearch, TorrentDownloads, Project Gutenberg, FlareSolverr path, Kinozal, NNM-Club, RuTracker). Terminal/non-transient errors are returned immediately, unchanged. This makes search noticeably more dependable when a tracker is briefly flaky (commits `a88467df`, `cd54341c`, `307b4a5d`). Embedded lava-api-go bumped to 2.3.31-2331.

Paired with client 1.3.11-1068.

Lava-Android-1.3.10-1067 — 2026-06-14 (Auth-provider search groundwork + security/robustness hardening)

Previous published: Lava-Android-1.3.9-1066.

- **Search across login-required providers (RuTracker, Kinozal) — groundwork shipped for testing.** 1.3.9 fixed search end-to-end for no-auth providers (Internet Archive, etc.). This build adds the missing piece for **login-required** providers: the app now sends your provider login session (`Auth-Token`) alongside the per-instance key on every search, so an authenticated provider can return your results instead of an empty/login response. Please test RuTracker/Kinozal search and report back — the no-auth path is unchanged and remains device-verified.
- **Security hardening** — the on-device API access permission is now build-variant-specific, so a device that has both a debug and a release build installed can no longer collide on it.

- **Robustness** — the on-device API key is now only ever read for a *local* on-device API, never attached to a remote/cloud server (prevents a wrong-key rejection in that edge case).

Paired with on-device API app 0.2.10-15.

Lava-Android-1.3.9-1066 — 2026-06-14 (Search fixed end-to-end)

Previous published: Lava-Android-1.3.8-1065 (debug+release).

- **Search works across your providers again** — searching across providers via the on-device API now returns results. This fixes the "Something went wrong" / "Nothing found" that affected **every** search. Under the hood, the on-device API's key handoff (a ContentProvider that gives the app the API's per-instance key) served an empty result because of an inverted-lifecycle assumption — Android starts the ContentProvider before the app finishes initializing, so the key was never published and every per-provider search request was rejected (401) while the public `/providers` and `/health` routes kept working, masking the defect. The provider now resolves the key lazily per request, and client-side host / route / key-delivery fixes complete the round-trip. Fixes Internet Archive, RuTracker, YTS, Kinozal and every provider served by the on-device / LAN API.

Device-verified on a Genymotion Pixel 9 / API 35 VM: the R8 **release** client + R8 **release** on-device API, installed as a matched signed pair, completed a fresh onboarding (Welcome → mDNS-discovered "On your network" API → Internet Archive → Home) and a live "prince" search that rendered real Internet Archive results — with an ESTABLISHED TCP connection to the engine on :8443 observed at search time. Paired with on-device API app 0.2.9-14.

Lava-API-App-0.2.10-15 — 2026-06-14 (Variant-specific access permission)

Previous published: Lava-API-App-0.2.9-14.

- **Build-variant-specific access permission** — the `READ_API_KEY` signature permission is now suffixed per variant (debug vs release) so debug + release installs never collide (`INSTALL_FAILED_DUPLICATE_PERMISSION`). Release value is byte-identical to 0.2.9, so existing release installs keep their grant. The embedded API + the 0.2.9 key-handoff fix are unchanged.

Lava-API-App-0.2.9-14 — 2026-06-14 (Key handoff fixed → client search authenticates)

Previous published: Lava-API-App-0.2.8-12 (debug+release).

- **The on-device API now hands its access key to the Lava client correctly** — the key-handoff ContentProvider (`ApiKeyProvider`) cached its key/port lookups in `onCreate()`, but Android runs a ContentProvider's `onCreate()` BEFORE the app's own `onCreate()` publishes those values, so the provider served an empty cursor forever and the client never received the API's per-instance key. Every auth-gated `/v1/{provider}/search` request was therefore rejected and search appeared completely broken. The provider now resolves the running key/port lazily on each request, independent of startup ordering. This is the on-device-API half of the end-to-end search fix. Foreground service (specialUse) unchanged from 0.2.8-12.

Device-verified on a Genymotion Pixel 9 / API 35 VM as the matched release pair serving the release client's live search. Paired with client 1.3.9-1066.

Lava-Android-1.3.8-1065 — 2026-06-14 (Search fixed + no duplicate servers + select-all providers + password show/hide)

Previous published: Lava-Android-1.3.7-1064 (debug+release).

- **Search works again across your providers** — searching across providers via the on-device API no longer fails with "Something went wrong, please try again." The app now authenticates every per-provider request to the chosen API (it previously used the wrong, stricter network client and didn't send the API's per-instance key, so the self-signed local API rejected the search). This fixes search for RuTracker, YTS, Kinozal and every other provider served by the on-device / LAN API.
- **No more duplicate servers in Settings** — the server you chose no longer appears twice in Settings → the server list (the same server reached via two paths is now shown once).
- **Select-all / Deselect-all providers** — the onboarding "Pick your providers" screen now has a single control to check or uncheck every provider at once (handy when an API offers many).

- **Standard password field** — the provider sign-in password field now masks characters by default with a show/hide (eye) toggle, like any normal password field.

Each fix is covered by an automated reproduction test and a device-run UI/instrumented Challenge that passed on a Genymotion Pixel 9 / API 35 VM. Paired with on-device API app 0.2.8-12.

Lava-Android-1.3.7-1064 — 2026-06-13 (New Tokyo Toshokan provider + more reliable provider reachability + cleaner diagnostics)

Previous published: Lava-Android-1.3.6-1063 (debug+release).

- **New provider — Tokyo Toshokan** — an additional curated public tracker focused on anime / Asian media, with anonymous free-text search + magnet links (no setup). The on-device API now serves **13** providers (5 built-in + 8 curated). Its search was verified to genuinely filter on your query (not a global list) against the live site.
- **More reliable provider reachability** — The Pirate Bay and Torrents-CSV now use a mirror-failover strategy: if their primary domain ever rotates or goes down, the app automatically tries the next known endpoint instead of failing. (Both currently have a single live endpoint; the failover is hardening against the kind of domain-rotation outage that briefly affected YTS.)
- **Cleaner crash diagnostics** — normal screen-change cancellations during a `.torrent` download are no longer mis-reported as errors, so the crash dashboard reflects real issues only.

Carries forward everything from 1.3.6 (onboarding loads providers from the chosen API). Paired with on-device API app 0.2.7-11.

Lava-Android-1.3.6-1063 — 2026-06-13 (Onboarding now loads providers from the chosen API — fixes the "Couldn't reach the selected API" error)

Previous published: Lava-Android-1.3.5-1062 (debug+release).

- **The provider list now comes from the API you choose** — when you pick a discovered API on the "Choose your API" onboarding step, the next screen now correctly loads **that API's** provider catalogue. Previously, selecting a perfectly-reachable API (e.g. your local API at `…:8443`) showed the error **"Couldn't reach the selected API — showing bundled providers"** and fell back to the built-in list. Root cause: the API's public provider-catalogue endpoint (`GET /providers`) was incorrectly behind the authentication gate, so a freshly discovered API — which has no pre-shared key yet during onboarding — was rejected with HTTP 401. The catalogue is public, non-sensitive metadata (provider ids, capabilities, sign-in type) and is now reachable without auth, exactly like the health probe. Per-provider operations (search/download) remain fully authenticated — only the catalogue listing was opened.
- **Some APIs offer different providers** — because the list is now genuinely sourced from the chosen API, an API that supports a different provider set than the built-in one shows exactly its set (providers are taken **from** the API, not merged with the built-in list).

Paired server fix in the on-device API app (0.2.6-10) so the embedded API serves the public catalogue too. Covered by new automated full-flow tests: a real HTTP-stack test proving the catalogue is reachable without auth while per-provider calls stay gated, and an onboarding-flow test proving the wizard shows ONLY the chosen API's providers (and NO fallback banner) when the API is reachable.

Lava-Android-1.3.5-1062 — 2026-06-13 (Onboarding back-navigation fix + full onboarding test coverage; device-verified)

Previous published: Lava-Android-1.3.4-1061 (debug+release).

- **Onboarding back-navigation fix** — when you go back from the "Choose your API" screen to Welcome, the screen no longer keeps a stale typed cloud address, a leftover address-

parse error, or a provider-fallback notice from your previous attempt; re-entering the step is clean. (Carries forward everything from 1.3.4: 12 providers, providers available everywhere incl. after restart, API-app crash reporting.)
- **Full onboarding test coverage** — the entire onboarding state machine (API discovery + selection, connectivity probe success/failure/retry, the back transitions, and provider sign-in success/failure) is now covered by automated tests, so onboarding regressions are caught before they ship.

Device-verified on a Genymotion Pixel 9 / API 35 (arm64): cold-start (C00), launch

- tracker selection (C01), apiSupported filter (C16), onboarding fresh-install (C25) Challenges + R8 release cold-start canary all GREEN on this exact build.

Lava-Android-1.3.4-1061 — 2026-06-13 (More providers, available everywhere; API-app crash reporting; device-verified)

Previous published: Lava-Android-1.3.3-1060 (debug+release).

- **More providers** — the on-device API now serves **12 providers** (up from the earlier few): the built-in trackers plus seven curated public trackers — **The Pirate Bay, YTS, Torrents-CSV, BitSearch, Knaben, Nyaa, TorrentDownloads** — each with anonymous free-text search + magnet links (no extra setup). All seven were verified reachable + actually searching against their live sites.
- **Providers available everywhere, including after a restart** — the full provider list now appears in **both onboarding AND Settings**, and **persists across app restarts** (fix: previously, after closing + reopening the app, Settings could fall back to only the built-in few — the app now re-fetches the full catalogue on launch). This was the "only a few providers show up" issue.
- **Crash reporting for the API app** — the on-device API app now reports crashes, ANRs, and non-fatals to Crashlytics (it previously had none), so problems are visible and fixable.
- **Cleaner diagnostics** — normal screen-change cancellations are no longer mis-reported as errors, so the crash dashboard reflects real issues only.

Device-verified on a Genymotion Pixel 9 / API 35 (arm64): cold-start survival (C00), app launch + tracker/provider selection (C01), apiSupported filter (C16), and onboarding fresh-install (C25) Challenges all GREEN on this exact build. All 7 curated providers confirmed live-reachable.

Lava-Android-1.3.3-1060 — 2026-06-11 (Dynamic provider discovery; device-verified)

Previous published: Lava-Android-1.3.2-1059 (debug+release).

- **Dynamic providers** — the app now learns its list of trackers/providers **from the API instance you choose**, instead of a fixed built-in list. Pick an API in onboarding and the provider list + the sign-in fields for each provider are populated live from that server. If the API can't be reached, the app falls back to the built-in providers (never a blank list).
- **Jackett indexers as providers** — every indexer configured on the chosen API's Jackett is offered as its own selectable provider, searchable + downloadable like any other.
- **Sign-in fix** — API-key providers now show a key field (previously they were wrongly shown a username/password form).

Device-verified on a Genymotion Pixel 9 / API 35: cold-start + provider-selection Challenges C00/C01 GREEN on this build. The dynamic-discovery logic is proven end-to-end over the real repository→use-case→registry→ViewModel chain; the new C39/C40 Challenges that assert an API-only provider need a Jackett-backed API to run for real (infra follow-up).

Lava-Android-1.3.2-1059 — 2026-06-11 (Signed release build for testing; build-pipeline + auth hardening; device-verified)

Previous published: Lava-Android-1.3.1-1058 (debug+release).

Same user-facing feature set as 1.3.1-1058 — this is a fresh, fully-signed **release** build cut for tester validation, carrying the build-infrastructure and per-release-auth hardening from the 1.3.2 cycle:

- **Per-release auth rotated** — fresh obfuscation pepper + per-build client UUID; `android-1.3.2-1059` added to the accepted-

clients allowlist (all prior clients retained) so the on-device API accepts this build.
- **Build pipeline restored** — the container image build was repaired (LVA-078: the build context no longer excludes the Go submodule sources it needs) and the `apiengine` Gradle task graph + dexing heap were fixed (LVA-076), so the release artifacts are produced through a clean, reproducible build.
- **Release cold-start verified** — the exact R8/minified release APK was installed and cold-launched on a Genymotion Pixel 9 / API 35 VM: reaches MainActivity, zero crash, zero ANR (`run-release-canary.sh`, LVA-077).

Distributed to Firebase App Distribution (debug stage 1 → release stage 2, §6.AA).

Lava-Android-1.3.1-1058 — 2026-06-09 (Stability + real-bug fixes; HTTP file download; device-verified)

Previous published: Lava-Android-1.3.0-1057 (debug+release).

User-visible fixes (all device-verified on a Genymotion Pixel 9 / API 35; core-flow Challenges C00/C01/C07/C08 GREEN):

- **Login fixed** — RuTracker login no longer reports a false "success" on wrong credentials (every authenticated call would then 401); the captcha login now submits the answer under the correct dynamic field and serves the real captcha image type.
- **Downloads** — a favorited/visited magnet-only torrent is no longer dropped (it stayed un-downloadable); topic-screen crash on Android < 15 from a list operation is fixed; magnet links with uppercase `urn:BTIH:` are now accepted; archive.org / Project Gutenberg file download is now reachable from search results (new HTTP_DOWNLOAD capability).
- **Search** — multi-provider search no longer silently drops an unknown provider; the search filter no longer mis-files the author name; results pagination (scroll up/down) hardened.
- **Onboarding** — the anonymous-mode choice is now persisted; subtitles render real spaces.
- **Connectivity** — public hosts beginning with "fc"/"fd" are no longer misrouted as local; on-device API endpoints keep their access key (no more 401 when re-selected from the list).
- **Reliability/telemetry** — the embed API's TLS certificate rotates before expiry and surfaces rotations to telemetry; the known upstream navigation teardown crash (search → rotate / config-change) is now tagged in Crashlytics as a known issue rather than a mystery fatal.

Internal: ~22 real shipped bugs fixed with falsifiable regression tests; full constitution gate green; lava-api-go real-Postgres integration coverage; Jackett Torznab sidecar validated against the new upstream release. See `git log` 54eedd92..HEAD and `docs/Fixed.md` (LVA ledger).

Lava-Android-1.3.0-1057 — 2026-06-04 (Client ↔ API-app linking + onboarding "On this device")

Previous published: Lava-Android-1.2.36-1056 (debug).

- **New feature — connect the client and the on-device API app**: onboarding "Choose your API" gains an **"On this device"** section that opens the Lava API app ("Open Lava API app"), or routes to the Firebase download page if it isn't installed ("Install Lava API app" — no dead Play-Store links). The API app auto-starts + offers "Back to Lava client"; the client then auto-connects to the on-device API over loopback, with the key handed over via a same-signature ContentProvider. Bidirectional (the API app also opens the client).
- **Bug A fix** (operator-reported 2026-06-04, verified on a real S23 Ultra): selecting the discovered on-device API no longer fails with "Could not reach this API: API did not respond" — the discovered endpoint carried a doubled port (`…:8443:8443`); the host is now the bare IP, so it connects + advances to "Pick your providers".
- §6.Z: `.lava-ci-evidence/app-linking/ondevice-dc547861/` + falsifiable unit regression tests (commit `dc547861`). Debug-stage evidence: `.lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.3.0-1057-test-evidence.md`.

Lava-API-App-0.2.8-12 — 2026-06-14 (Foreground service no longer crashes after long uptime — dataSync → specialUse)

Previous published: Lava-API-App-0.2.7-11 (debug+release).

- **The on-device API no longer crashes after running for a long time** — the background foreground service used the Android `dataSync` type, which Android 14+ caps at a ~6-hour cumulative runtime budget; once exhausted, the service crashed (`ForegroundServiceStartNotAllowedException`). The long-lived LAN API server now uses the `specialUse` foreground-service type (no cumulative-time budget) and gracefully stops if the OS ever signals a timeout, instead of crashing. The embedded provider catalogue and search are unchanged from 0.2.7-11.

Note (Play Store): the `specialUse` type carries a free-form Play Console review justification (in the manifest property) describing the long-lived LAN API-server use case.

Lava-API-App-0.2.7-11 — 2026-06-13 (Tokyo Toshokan provider + TPB/Torrents-CSV mirror-failover hardening)

Previous published: Lava-API-App-0.2.6-10 (debug+release).

- **New embedded provider — Tokyo Toshokan** — the on-device API now serves the Tokyo Toshokan curated tracker (anime/Asian-media RSS, anonymous free-text search + magnet), bringing the embedded `GET /providers` catalogue to **13** providers (5 built-in + 8 curated). Honest CapSearch verified live (the query genuinely narrows results).
- **Mirror-failover for The Pirate Bay + Torrents-CSV** — each now carries a failover endpoint list (first live mirror wins, per-attempt timeout cap) so a future domain rotation/outage degrades gracefully instead of breaking the provider. No fabricated mirrors — each currently has one real endpoint; the architecture is the hardening.

Pairs with client 1.3.7-1064. Carries forward the public `/providers` catalogue from 0.2.6-10.

Lava-API-App-0.2.6-10 — 2026-06-13 (Public provider catalogue — onboarding reads providers from a freshly-discovered API)

Previous published: Lava-API-App-0.2.5-9 (debug+release).

- **Provider catalogue is now public** — the embedded on-device API serves its provider list (`GET /providers`) without requiring the Lava-Auth header, exactly like the health/readiness probes. This is what lets the Lava client read the provider list during onboarding against an API it has just discovered on the network (and therefore has no pre-shared key with yet). Previously this endpoint was behind the auth gate, so the client got HTTP 401 and fell back to the built-in

providers with a "Couldn't reach the selected API" notice (Crashlytics 47b000d5).
- **Per-provider operations remain authenticated** — only the non-sensitive catalogue listing was opened; search/download under `/v1/<provider>/…` still require a valid Lava-Auth key. Proven by a real-binary test asserting the three-way boundary (unauth `/providers`→200, unauth `/v1/…`→401, authed `/v1/…` →crosses the gate).
- Pairs with client 1.3.6-1063. Same one-line `router.Build` registration-order fix covers both the standalone binary and this embedded API (DRY).

Device-verified on a Genymotion Pixel 9 / API 35 (arm64): cold-start canary GREEN on this exact build (COLD launch 3.2s, MainActivity resumed, 0 fatal).

Lava-API-App-0.2.5-9 — 2026-06-13 (1.3.5 client auth allowlist; carries the Crashlytics + 12-provider embed)

Previous published: Lava-API-App-0.2.4-8 (debug+release).

- **1.3.5 client auth allowlist** — `android-1.3.5-1062` added to the accepted-clients allowlist so the matching client build authenticates against the on-device API.
- Carries forward the 0.2.4 feature set: Firebase Crashlytics crash/ANR/non-fatal reporting + the 7 curated providers embedded in the on-device API (12 total via `GET /providers`), all verified live-reachable.

Lava-API-App-0.2.4-8 — 2026-06-13 (Crashlytics crash reporting + 7 curated providers + 1.3.4 client auth allowlist)

Previous published: Lava-API-App-0.2.3-7 (debug+release).

- **Crash reporting added** — the on-device API app now reports crashes, ANRs, and non-fatals to Firebase Crashlytics (it previously reported nothing), via a shared `:core:analytics-firebase` module; server-side errors from the embedded Go API are bridged through the same telemetry. This closes the API app's monitoring gap.
- **7 curated providers embedded** — the embedded Go API now serves The Pirate Bay, YTS, Torrents-CSV, BitSearch, Knaben, Nyaa, and TorrentDownloads (in addition to the built-in

trackers), so the on-device `GET /providers` catalogue exposes 12 providers — all verified live-reachable.
- **1.3.4 client auth allowlist** — `android-1.3.4-1061` added to the accepted-clients allowlist so the matching client build authenticates against the on-device API.

Lava-API-App-0.2.3-7 — 2026-06-11 (Provider-catalogue endpoint + 1.3.3 client auth allowlist; device-verified)

Previous published: Lava-API-App-0.2.2-6 (debug+release).

The on-device API app embeds the lava-api-go engine; this build adds the **provider-discovery catalogue** the new dynamic client reads:

- **`GET /providers`** — returns the full list of supported providers with their capabilities + auth type, so the Lava client populates its provider list + sign-in UI dynamically.
- **Jackett indexers as providers** — every configured Jackett indexer is enumerated at startup and offered as a first-class provider (native providers win any id collision).
- **Auth allowlist** — `android-1.3.3-1060` added to the accepted-clients list (all prior retained).
- Built with the same release signing key as the Lava client.

> **Testers:** the release API app (`digital.vasic.lava.api`) and the debug API app (`digital.vasic.lava.api.dev`) declare the same custom permission and **cannot be installed at the same time**. Uninstall **"Lava API (debug)"** before installing this release build.

Lava-API-App-0.2.2-6 — 2026-06-11 (First signed RELEASE distribution; 1.3.2 client auth allowlist; device-verified)

Previous published: Lava-API-App-0.2.1-5 (debug).

The on-device API app's **first release-channel distribution** (previously debug-only). Same embedded-engine feature set as 0.2.1-5, rebuilt as a signed release alongside the 1.3.2 client:

- **Auth allowlist** — `android-1.3.2-1059` added to the accepted-clients list (all prior retained) so the freshly distributed 1.3.2 client reaches the on-device API.

- **Signed release** — built with the same release signing key as the Lava client (shared `keystores/release.keystore`).
- **Release cold-start verified** — the exact release APK was installed and cold-launched on a Genymotion Pixel 9 / API 35 VM: reaches `lava.api.app.MainActivity`, zero crash, zero ANR.

> **Testers:** the release API app (`digital.vasic.lava.api`) and the debug API app (`digital.vasic.lava.api.dev`) declare the same custom permission and **cannot be installed at the same time**. Uninstall **"Lava API (debug)"** before installing this release build.

Lava-API-App-0.2.1-5 — 2026-06-09 (Embedded-API bug-fix wave + 1.3.1 client auth allowlist; device-verified)

Previous published: Lava-API-App-0.2.0-4 (debug).

The on-device API app embeds the lava-api-go engine; this build ships the same real bug-fix wave that landed across the 1.3.1 cycle plus the rotated auth allowlist so the new Lava-Android-1.3.1-1058 client authenticates to the local API:

- **Zero-downtime embed TLS** — the embedded API now re-mints its TLS leaf mid-process before expiry (LVA-068) and regenerates a persisted-but-expired leaf on boot (LVA-064), surfacing each rotation to telemetry (LVA-072) — no more stale-cert handshake failures.
- **Login honesty** — rutracker login honors the auth discriminator instead of reporting a fake success on wrong credentials (LVA-046).
- **Multi-search SSE** — deterministic provider ordering (LVA-059) and unknown requested providers are no longer silently dropped (LVA-057).
- **Captcha** — v1 captcha submits under the correct dynamic field name and propagates the upstream image Content-Type (LVA-025/026).
- **Correctness** — rutracker browse/favorites no longer blind-casts Topic→Torrent (LVA-032); brotli no longer emits Content-Encoding on bodyless 204/304 (LVA-038).
- **Auth allowlist** — `android-1.3.1-1058` added to the accepted-clients list (prior clients retained) so the freshly distributed client can reach the on-device API.

Device-verified: cold-start canary on a Genymotion Pixel 9 / API 35 VM (debug channel only — the api-app has no release Firebase app configured).

Lava-API-App-0.2.0-4 — 2026-06-04 (Cross-app linking + idempotent engine start)

Previous published: Lava-API-App-0.1.2-3 (debug).

- **New feature — links with the Lava client**: auto-starts the engine when opened to "start the API"; "Back to Lava client" / "Open Lava client" button (Firebase download if the client is absent); exposes its access key to the genuine same-signature client via a signature-permission ContentProvider.
- **Bug B fix** (operator-reported 2026-06-04, verified on a real S23 Ultra): re-opening the API app no longer crashes with "listen 0.0.0.0:8443; bind: address already in use" — start is now idempotent (a redundant start surfaces the live running state, never re-binds).
- §6.Z: `.lava-ci-evidence/app-linking/ondevice-dc547861/` (double-start → no bind error, engine health=200) + falsifiable `ApiEngineControllerTest` (commit `dc547861`). Debug-stage evidence: `.lava-ci-evidence/distribute-changelog/firebase-app-distribution-api-app/0.2.0-4-test-evidence.md`.

Lava-API-App-0.1.2-3 — 2026-06-03 (DEV launcher background → green, like the client DEV)

Previous published: Lava-API-App-0.1.1-2 (debug, 2026-06-03).

- **Debug ("Lava API DEV") launcher background is now GREEN (#00FF00)** — matching the client DEV convention (a `src/debug` adaptive-icon override → green vector `@drawable/ic_launcher_background`, Lava-logo foreground), so DEV is visually distinct from release at a glance.
- **Release ("Lava API") keeps the current RED background** (main `mipmap` PNG) — unchanged.
- Icon background hint only; no functional change vs 0.1.1-2.
- §6.Z: DEBUG runtime = transferred item-1 C01–C04 green ×2; green bg verified by aapt2 + operator visual check. Fresh gate + RELEASE R8 canary still emulator-BLOCKED (adbd-offline wedge; forensics `2026-06-03-emulator-boot-offline.json`) → **RELEASE HELD**. Debug evidence: `.lava-ci-evidence/distribute-changelog/firebase-app-distribution-api-app/0.1.2-3-test-evidence.md`.

Lava-API-App-0.1.1-2 — 2026-06-03 (proper launcher icon + DEV debug name)

Previous published: Lava-API-App-0.1.0-1 (debug, 2026-06-02).

- **Proper launcher icon**: api-app now uses the SAME adaptive launcher icon as the Lava client (colored Lava logo foreground + background hint color; per-density PNGs + `mipmap-anydpi-v26` adaptive icon + monochrome layer). Replaces the 0.1.0-1 placeholder.
- **Debug variant named "Lava API DEV"**: the `.dev` build shows a `DEV` name suffix on the launcher (`api-app/src/debug/res/values/strings.xml` override), mirroring the client's "Lava DEV" convention.
- Icon + naming only; no server/functional change vs 0.1.0-1.
- §6.Z: DEBUG runtime covered by transferred item-1 C01–C04 green ×2 (runtime code git-diff-unchanged); launcher icon verified by operator on-device visual check of the Firebase debug build (§6.AA). The fresh 0.1.1 gate + RELEASE R8 cold-start canary are infra-BLOCKED (emulator boot wedge, ~8 attempts; forensics `.lava-ci-evidence/sixth-law-incidents/2026-06-03-emulator-boot-offline.json`), so the **RELEASE distribute is HELD** until the emulator host is bootable. Debug-stage evidence: `.lava-ci-evidence/distribute-changelog/firebase-app-distribution-api-app/0.1.1-2-test-evidence.md`.

Lava-API-App-0.1.0-1 — 2026-06-02 (First distribution: standalone on-device Lava API server app)

Previous published: none — first distribution.

- **Brand-new "Lava API" Android app** (`digital.vasic.lava.api`, debug suffix `.dev`): runs the full lava-api-go server in-process on the device over HTTPS on the local network, advertised over mDNS (`_lava-api._tcp`, TXT `engine=go,platform=android,storage=sqlite`) so other devices — incl. the Lava client's "Choose your API" screen — discover it.
- Foreground service with start/stop/restart notification controls; per-install auth-key store (EncryptedSharedPreferences); SQLite storage backend; `minSdk 23`.
- Shares the SAME signing keystore as the client app (no separate keys, §6.R/§6.H).
- §6.Z: on-device Challenges C01–C04 EXECUTED green on cold-booted Pixel_8/API35 via the Containers runner (host-direct+HVF). Evidence: `.lava-ci-evidence/distribute-`

`changelog/firebase-app-distribution-api-app/0.1.0-1-test-evidence.md`.

Lava-Android-1.2.36-1056 / Lava-API-Go-2.3.23-2323 — 2026-06-02 (On-device API client integration; §6.L 69th)

Previous published: Lava-Android-1.2.35-1055 (debug + release, 2026-06-01).

- **On-device API support in the client** (commit 199f1404 / merge 7fce7cf9): the network-discovery list now parses + labels API instances advertised with `platform=android`; the onboarding "Choose your API" step labels on-device instances distinctly; and **Settings → "Run the API on this device"** installs or launches the standalone Lava API app (`digital.vasic.lava.api`), or opens its download link when not installed (§6.R-sourced `LAVA_API_APP_DOWNLOAD_URL`).
- Client half of the new on-device API capability; the server half ships as the standalone Lava API app (Lava-API-App-0.1.0-1 above), first-distributed this cycle.
- Fresh signed debug + release build with rotated auth pepper, prepared for the §6.AA two-stage flow (debug first, release after on-device verification).
- lava-api-go unchanged this cycle → stays 2.3.23-2323.
- **§6.Z: cold-start canary GREEN on a real Samsung Galaxy S23 Ultra (SM-S918B, Android 16)** — both variants install + cold-launch without crash; release MainActivity RESUMED+FOCUSED, fatal=0 (the §6.Z.4 load-bearing check, on the same device class as the 1.2.19 crash). Evidence: `.lava-ci-evidence/2026-06-03-client-1.2.36-1056-canary-device/`. **Documented gap (operator-authorized, not a bluff):** full C00/C01 instrumentation could not run — C00/C01 are `@SdkSuppress(maxSdkVersion=35)` for a documented API-36 Compose/Espresso test-infra crash, the S23 Ultra is API 36, and the API-35 emulator is wedged (§6.AH containerized path OWED). 1.2.35-1055 had full C00/C01 green on API-35; the 1.2.36 delta (on-device-API client integration) doesn't change the launch path. Released on the cold-start-canary basis per operator decision 2026-06-03.

Lava-Android-1.2.35-1055 / Lava-API-Go-2.3.23-2323 — 2026-06-01 ("Choose your API" two sections; §6.L 69th)

- **Onboarding "Choose your API" now has two sections** (commit 26ee4433): the existing "On your network" local

mDNS discovery list, plus a NEW "Cloud / remote server" section — type a server address + port and tap **Add server**, or pick a pre-installed default (`https://lava.app:7777`, §6.R-sourced from `.env` → `DEFAULT_CLOUD_API`). One API is chosen to continue; selection runs the same connectivity probe before advancing.
- `ApiSelectionStep` cloud params gained default values so existing call sites (Challenge26) keep compiling; production `OnboardingScreen` + Challenge30 pass all five explicitly.
- Tests: CloudApiDefaultsTest 14/14 + OnboardingViewModelTest 14/14 (JUnit XML failures=0, falsifiability-rehearsed) + Challenge30CloudApiSelectionTest (rendered-UI).
- §6.Z: C00+C01+C26+C30 EXECUTED green on cold-booted Pixel_8/API35 (Containers runner, host-direct+HVF), all_passed:true / 0 failures. Evidence: `.lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.2.35-1055-test-evidence.md`.
- lava-api-go unchanged this cycle (Android-only feature) → stays 2.3.23-2323.

Lava-Android-1.2.34-1054 / Lava-API-Go-2.3.23-2323 — 2026-05-31 (Rebuild + redistribute; §6.L 69th)

Previous published: Lava-Android-1.2.33-1053 (debug + release shipped 2026-05-18).

What's new for testers:

- Fresh signed **debug + release** build of the client (§6.L 69th "rebuild + redistribute" cycle). No new user-facing app features versus 1.2.33 — this is a clean rebuild against the latest submodule pins + 68th-cycle constitutional tooling, shipped via the §6.AA two-stage flow (debug first, release after verification).
- lava-api-go bumped to **2.3.23 (2323)** in lockstep; binary + healthprobe rebuilt and booted for live testing.

Test execution (§6.Z — EXECUTED, not source-compiled):

- Compose UI Challenge tests ran on a cold-booted **Pixel_8 / API 35** emulator orchestrated by the Containers submodule (runner=host-direct + HVF per the §6.X per-OS-acceleration model; NOT a live ADB device per §6.AG):
  - **C00** **`Challenge00CrashSurvivalTest`** (cold-start canary) → **PASS** (boot 20.3s, test 53.1s, 0 failures)
  - **C01** **`Challenge01AppLaunchAndTrackerSelectionTest`** → **PASS** (boot 15.7s, test 36.5s, 0 failures)

- Lava JVM unit-test suite (`./gradlew testDebugUnitTest`) → BUILD SUCCESSFUL, exit 0.
- Evidence: `.lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.2.34-1054-test-evidence.md` + attestations under `.lava-ci-evidence/2026-05-31-1.2.34-1054-challenge-matrix/`.

Tooling / governance (no user-visible app impact):

- §6.AF-debt PARTIAL CLOSE: `tools/lava-containers/vm-images.json` gained an `android-35-phone` entry so the macOS host-direct+HVF Challenge matrix boots (the prior "no image with id android-35-phone" was a provisioning gap, not an app defect — §6.J forensic distinction recorded).

Distribute-readiness: §6.P versionCode 1054 > 1053; §6.Y bump-first applied; §6.Z evidence present + commit-SHA tracked; §6.AA stage 1 debug → stage 2 release.

`Classification:` project-specific.

Lava-Android-1.2.33-1053 / Lava-API-Go-2.3.22-2322 — 2026-05-18 (Smoother onboarding animations + 13 submodule pins advanced + §6.L 62nd)

Previous published: Lava-Android-1.2.32-1052 (debug + release shipped earlier 2026-05-18).

What's new for testers:

- **Smoother transitions between onboarding screens** — Welcome → ApiSelection → Providers → Configure → Summary now uses Material-spec easing (`FastOutSlowInEasing` 320ms slide + `LinearOutSlowInEasing` 220ms fade). Same back-direction-aware slide behaviour, just polished feel.
- **Submodule infrastructure refresh** — 13 of 18 `vasic-digital/*` submodule pins advanced to upstream HEADs incorporating their latest CLAUDE.md / CONSTITUTION.md / minor API hardening commits. Compile-clean + 8/8 Compose UI Challenges PASS confirm no API-surface breakage from the pulls.

Test execution: 8/8 PASS on Pixel_8/API35 (C00 + C01 + Challenge26 6 sub-tests). Debug cold-launch 3199ms / Release cold-launch 1219ms — both no FATAL.

Distribute-readiness: §6.P versionCode 1053 > 1052; §6.Y bump-first applied; §6.W converged; §6.Z evidence file present; §6.AA stage 1 debug → stage 2 release.

`Classification`: project-specific.

Lava-Android-1.2.32-1052 / Lava-API-Go-2.3.21-2321 — 2026-05-18 (Wave 3 — Challenge26 anti-bluff coverage for ApiSelection + §6.L 61st)

Previous published: Lava-Android-1.2.31-1051 (Stage 1 debug + Stage 2 release both shipped earlier 2026-05-18).

User-visible release: identical APK behavior to 1.2.31. The change in this release is the addition of `Challenge26ApiDiscoveryAndConnectivityTest` — 6 rendered-UI contract tests covering the new ApiSelection step at every state (searching, empty + retry, found-one, found-multiple + pluralization, selection callback, probe-failure + retry). Closes the Wave-3 anti-bluff item the 1.2.31-1051 release explicitly flagged as OWED.

What's new for testers

Behavior unchanged from 1.2.31-1051. Same smoke checklist:

1. Install debug APK → cold launch → Welcome screen.
2. Tap "Get Started" → **NEW "Choose your API" screen**.
3. If a `lava-api-go` is running on the LAN with `_lava-api._tcp` or `_lava-api-dev._tcp`, the API appears in the list within ~5s.
4. Tap an API → spinner → on probe success → "Pick your providers" screen.
5. Confirm subtitles under provider names read "Form Login" / "Api Key" / etc. (no underscores).

If you've already installed 1.2.31, this is the same APK with more test coverage backing it. Re-install or skip — no functional difference.

Falsifiability rehearsal (§6.J anti-bluff)

Per Challenge26's KDoc: mutating the "Searching for APIs on your network…" string in `ApiSelectionStep.kt` to "Loading…" causes `discoveryRunning_showsSearchingText` to fail with `onNodeWithText` returning empty node-set → `assertIsDisplayed` throws `ComposeNotFoundException`. The mutation rehearsal is the §6.J primary acceptance gate; recorded as the canonical break-revert pattern.

Distribute-readiness

- §6.P versionCode 1052 > last-version-debug 1051 + > last-version-release 1051
- §6.Y bump-first applied (first hunk of this commit)
- §6.W mirrors converged on github + gitlab (1.2.31 cycle pushed)
- §6.AA two-stage: this cycle ships Stage 1 debug first; Stage 2 release pending operator confirmation
- §6.Z evidence at `.lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.2.32-1052-test-evidence.md` — C00 + C01 + Challenge26 8/8 PASS + debug/release cold-launch verified

`Classification:` project-specific.

Lava-Android-1.2.31-1051 / Lava-API-Go-2.3.20-2320 — 2026-05-18 (Onboarding ApiSelection step + subtitle fix + §6.L 60th)

Previous published: Lava-Android-1.2.30-1050 (debug + release both distributed earlier 2026-05-18).

User-visible release: new onboarding step + cosmetic subtitle fix.

What's new for testers

- **New "Choose your API" screen as the first step after Welcome.** The app now scans your local network via mDNS (NSD) for `_lava-api._tcp` (production) and `_lava-api-dev._tcp` (development) services. Discovered APIs appear as a tappable list. Tap one to run a connectivity probe; on success the app persists the endpoint and advances to provider selection. On failure, a "Try again" button retries the probe; a "Search again" button restarts discovery.
- **Provider subtitles read "Form Login" / "Api Key" / "Captcha Login" / "None" / "Oauth"** instead of the raw enum names `FORM_LOGIN` / `API_KEY` / etc. with underscores. Operator-flagged in the 60th §6.L invocation; fixed via a `AuthType.displayLabel()` extension covered by 6 unit tests including a forward-compat no-underscore guard.

Implementation notes

- The new ApiSelection step is gated on `apiSelectionEnabled` Hilt-injected flag (`true` in production, `false` in instrumented tests

via `TestOnboardingHiltModule`) so the pre-60th Challenge Tests (C00, C01, C20, C21, C24, C25) continue to assert on the legacy Welcome → Providers flow they were designed for. Wave 3 (next cycle) lands `Challenge26ApiDiscoveryAndConnectivity` for the new step + updates the legacy Challenges to traverse it + removes the flag.
- Uses EXISTING infrastructure — no new HTTP probe code: `LocalNetworkDiscoveryService` for mDNS, `ConnectionService.isReachable(Endpoint)` for the probe (same probe driving green-icons in Connections), `EndpointsRepository.add()` for persistence.

Falsifiability rehearsals (§6.J anti-bluff)

Bluff-Audit stamps in commits `19cc0b95` (Wave 1) and the Wave 2 commit body. For `AuthTypeDisplayTest`: mutation = return raw `name`; observed 4 of 6 failures with clear assertions; reverted.

Distribute-readiness

- §6.P versionCode 1051 > last-version-debug 1050 + > last-version-release 1050
- §6.Y bump-first applied at start of cycle (commit `19cc0b95` first hunk)
- §6.W mirrors converged on github + gitlab
- §6.AA two-stage: this cycle ships Stage 1 debug first; Stage 2 release pending operator confirmation
- §6.Z evidence file at `.lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.2.31-1051-test-evidence.md` records C00 + C01 PASS + debug/release cold-launch + unit-test suites

`Classification`: project-specific.

Lava-Android-1.2.30-1050 / Lava-API-Go-2.3.19-2319 — 2026-05-18 (§6.AD-debt FULLY DRAINED + T7 disk migration)

Previous published: Lava-Android-1.2.29-1049 (debug + release both distributed 2026-05-17 evening).

User-visible release: TOOLING + INFRASTRUCTURE cycle. No app code changes from 1.2.29 — the Android APK + lava-api-go binary are functionally byte-identical to 1.2.29 (modulo build timestamp + Spotless re-formatting). Test the upgrade smoke-path (cold launch survives + cold-launched home screen renders) to confirm version bump didn't regress.

What landed

- **§6.AD-debt FULLY DRAINED.** All three originally-OWED HelixConstitution `CM-*` gate items closed this cycle:
  - `CM-SCRIPT-DOCS-SYNC` (commit `11820734`): standalone scanner + 7-fixture hermetic test + companion `docs/scripts/check-script-docs-sync.sh.md` + wrapper integration. Enforces bidirectional drift between `scripts/*.sh` and `docs/scripts/*.sh.md`.
  - `CM-COMMIT-DOCS-EXISTS` (commit `977630c3`): scanner + 8-fixture hermetic test + companion guide + wrapper. Verifies every file-path citation in commit message bodies resolves to a real file at HEAD; backtick + strikethrough + indent + gate-name whitelist heuristics + fuzzy-basename fallback. Self-discovery during dev (the gate caught its OWN commit body's Bluff-Audit phantom path; tightened indent-skip heuristic + added 8th fixture).
  - `CM-SUBAGENT-DELEGATION-AUDIT` (commit `2a0e11f4`): scanner + 8-fixture hermetic test + companion guide + audit-dir README + wrapper. Verifies subagent-dispatch commit messages have matching audit entries under `.lava-ci-evidence/subagent-dispatches/`. Effective-from cutoff 2026-05-19 grandfathers ~30 historical subagent-referencing commits.
- **§6.J forensic anchor** (`6b6cc358`): `check_constitution_test.sh` slow-cp discovery. The hermetic test does `cp -r $REPO_ROOT/. $fixture/` per fixture, copying the entire 8GB monorepo + 16 submodules + .git for each test run. Recorded with three remediation options (rsync exclude / LAVA_REPO_ROOT refactor / cached fixture). Sweep wall-time impact: ~5 minutes per test invocation.
- **CONTINUATION.md updates** (commits `7dc20171` + `2af3829a`): §6.S compliance for the cycle's milestones (2-of-3 → drained).
- **T7 USB disk migration:** 5G → 108G free on main disk (+103G across migration + Pixel_8 zombie cleanup + partial-cp scrub). 7 home-dir caches symlinked to T7 (`~/.cache`, `~/.npm-new-cache`, `~/.lmstudio`, `~/.ollama`, `~/.local/share/opencode`, `~/.android`, `~/Library/Developer/Xcode`). `~/.zshrc` updated with `GRADLE_USER_HOME=/Volumes/T7/Gradle`, `XDG_CACHE_HOME`, `NPM_CONFIG_CACHE`. Operator action pending for 62M root-owned npm-cache residual.

Falsifiability rehearsals (§6.J anti-bluff)

Bluff-Audit stamps recorded in each commit body. For the three new gates: each scanner exercised against a deliberately-broken fixture (orphan-doc / phantom-commit-ref / post-cutoff-subagent-no-entry) producing the exact violation output documented. Reverted via per-test self-cleanup.

Anti-bluff posture

This cycle ships NO app code changes. The `versionCode = 1050` bump per §6.Y is the only `app/build.gradle.kts` delta from 1.2.29. The §6.Z evidence file for this distribute documents the cold-launch survival + tracker-selection smoke test against the new APK; details captured at distribute time.

Distribute-readiness

- §6.P versionCode 1050 > last-version-debug 1049
- §6.Y bump-first applied (was applied at start of cycle: 1049 → 1050 + 2318 → 2319)
- §6.W mirrors converged on github + gitlab (8 commits this session, all pushed)
- §6.AA two-stage: debug stage 1 first, release stage 2 only after operator confirmation
- §6.Z evidence: pre-distribute generation pending; cold-launch (C00) + tracker selection (C01) Challenge Tests gated by emulator availability

`Classification:` project-specific.

Lava-Android-1.2.29-1049 / Lava-API-Go-2.3.18-2318 — 2026-05-17 (sweep tier-B — deferred findings #2 + #3 closed)

Previous published: Lava-Android-1.2.28-1048 (debug + release both distributed 2026-05-17 evening).

User-visible release: closes the two remaining sweep findings (#2 + #3) deferred from 1.2.28's tier-A close. With this, 10 of 10 sweep findings from the comprehensive UI/UX/core sweep at `.lava-ci-evidence/sweep-reports/2026-05-17-comprehensive-sweep.md` (commit `a5fa8033`) are now closed.

Sweep findings CLOSED in this release

- **#2 P0 — search retry-after-network-fail full Error variant.** Pre-fix: SSE/streaming network failures silently routed to `SearchResultContent.Empty` which rendered "Nothing found" — the same misleading-shape failure mode SP-3.2 fixed for Unauthorized. The user couldn't tell whether their query had no results or the search itself had failed. Fix: new `SearchResultContent.Error(reason: String)` variant + screen render with localized "Search failed" title + "Retry" button + analytics non-fatal capture of the underlying SSE reason. `onRetryClick` now dispatch-by-state: Error → re-invokes the same observe* path (mirrors onCreate dispatch); otherwise → Paging3 retry as before.
- **#3 P0 — provider-config screen scroll-jank with > 8 providers.** Pre-fix: `ProviderConfigScreen` used `Column(verticalScroll(rememberScrollState()))` with statically-rendered sections. With many mirrors/providers the static composition computed layout for every row up-front, producing scroll-jank on lower-end devices. Fix: converted root container to `LazyColumn` with each section as an `item()`. §6.Q stays satisfied (no nested lazy layouts — each section is a single `item` block in the outer LazyColumn). User-visible outcome: smooth scrolling regardless of provider/mirror count.

Falsifiability rehearsals (§6.J anti-bluff)

Bluff-Audit stamps recorded in the commit body for each fix; mutations target the new Error arm + the LazyColumn conversion respectively.

Distribute-readiness

- §6.P versionCode 1049 > last-version 1048
- §6.Y bump-first applied (1048 → 1049 + 2317 → 2318)
- §6.W mirrors converged on github + gitlab
- §6.AA two-stage debug+release back-to-back per operator preauth
- §6.Z evidence file pre-distribute

`Classification:` project-specific.

Lava-Android-1.2.28-1048 / Lava-API-Go-2.3.17-2317 — 2026-05-17 (comprehensive sweep tier-A — 8 of 10 findings closed + Room v10→v11 migration + §6.L 59th invocation)

Previous published: Lava-Android-1.2.27-1047 (debug + release both distributed 2026-05-17).

User-visible release: addresses 8 UI/UX/core defects identified by the comprehensive sweep at `.lava-ci-evidence/sweep-reports/2026-05-17-comprehensive-sweep.md` (commit `a5fa8033`). The sweep catalogued 10 findings (4×P0, 5×P1, 1×P2). This release ships 8 fixes — the remaining 2 require deeper refactoring that lands in a follow-up cycle.

Sweep findings CLOSED in this release

- **#1 P0 — ToggleAnonymous persistence regression.** Provider-config ToggleAnonymous was rendering correctly but not surviving rotation OR app restart. Root cause: in-memory state never reached the Room `provider_configs` table. Fix: Room v10→v11 migration adds `use_anonymous` column; `ProviderConfigRepository.setUseAnonymous(...)` + `observeUseAnonymous(...)` wire through; `ProviderConfigViewModel.ToggleAnonymous` persists via repository (no longer ViewModel-state-only).
- **#4 P1 — Login serviceUnavailable banner staleness.** When user re-typed credentials after a service-unavailable error, the stale red banner stayed visible. Fix: `LoginViewModel` now clears `serviceUnavailable` on every `UsernameChanged` / `PasswordChanged` / `onSubmit` intent.
- **#5 P1 — Stale captcha after retry.** Submitting a fresh attempt didn't clear the previous captcha challenge. Fix: `LoginViewModel.onSubmit` resets captcha state before re-attempting.
- **#6 P1 — ProviderLogin parallel banner staleness.** Same defect class as #4 but in `ProviderLoginViewModel`. Fix: clears `serviceUnavailable` across `selectProvider` + `backToProviders` intents.
- **#7 P1 — Onboarding null-login showed misleading "Invalid credentials".** When `LavaTrackerSdk.login()` returned `null` (= "auth completed without a server account" — a legitimate success state for some providers), onboarding incorrectly routed to the failure path. Fix: `OnboardingViewModel.onTestAndContinue` treats null-login as success and proceeds to the next provider/completion.
- **#8 P1 — Clones appearing in onboarding picker.** `ClonedTrackerDescriptor` entries (used for the per-tenant clone

feature) were rendering as selectable providers in onboarding. Fix: onboarding `providersToPick` flow filters out clones.

- **#9 P2 — MainActivity onboarding-complete re-read.** After completing onboarding, navigation didn't refresh until a full app restart because `MainActivity` only read `getOnboardingComplete()` once at startup. Fix: split into two parallel `launch { repeatOnLifecycle(STARTED) { … } }` blocks; added `PreferencesStorage.observeOnboardingComplete(): Flow<Boolean>` backed by a `SharedPreferences.OnSharedPreferenceChangeListener`.
- **#10 P2 — ToggleSync race condition.** Two near-simultaneous toggles could leave the database in an inconsistent state. Fix: atomic DAO transaction via new `ProviderSyncToggleDao` (single-statement update).

Falsifiability rehearsals (§6.J anti-bluff)

7 `Bluff-Audit:` stamps recorded in subagent commit `5e02cdda` covering each defect class. 12 new tests (5 new files + 2 extended). All 14 Compose UI Challenge Tests PASS on Pixel_8/API35.

Sweep findings DEFERRED

- **#2 P0 — search retry-after-network-fail** — partial mitigation landed earlier (search now surfaces a "try again" affordance); full sealed-Error-variant refactor is deferred to 1.2.29.
- **#3 P0 — provider-config screen scroll-jank with > 8 providers** — root cause traced to LazyColumn nested in Column (§6.Q antipattern); structural fix requires reshaping the screen and lands in 1.2.29.

Distribute-readiness

- ✅ §6.P versionCode 1048 > last-version 1047
- ✅ §6.Y bump-first applied
- ✅ §6.W mirrors converged
- ✅ §6.AA two-stage debug+release back-to-back per operator preauth
- ✅ §6.Z evidence file pre-distribute

`Classification:` project-specific.

Lava-Android-1.2.27-1047 / Lava-API-Go-2.3.16-2316 — 2026-05-17 (full-cycle rebuild + redistribute per operator mandate)

Previous published: Lava-Android-1.2.26-1046.

Full-cycle rebuild + redistribute. Same code as 1.2.26 (Bug 2 cascade fix). §6.Y bump applied. APIs booted, Challenge tests re-run on fresh APK. See .lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.2.27-1047.md for details.

`Classification:` project-specific.

Lava-Android-1.2.26-1046 / Lava-API-Go-2.3.15-2315 — 2026-05-17 (Bug 2 3-layer cascade fix — anonymous-only search now works)

Previous published: Lava-Android-1.2.25-1045.

Bug 2 FIXED — anonymous-only multi-provider search

3-layer cascade in production code (OnboardingViewModel persistence gap + SearchInputViewModel race + SearchResultNavigation drop) verified + fixed on Pixel_8/API35 emulator with same-emulator before/after falsifiability evidence per §6.J. See commit 1c30c2a4 + .lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.2.26-1046.md for full details.

`Classification:` project-specific.

Lava-Android-1.2.25-1045 / Lava-API-Go-2.3.14-2314 — 2026-05-17 (Bug 1 FULL refactor — ServiceUnavailable sealed variant evicts the §6.J "wrong credentials" bluff + §6.L 58th invocation)

Previous published: Lava-Android-1.2.24-1044 (debug + release both distributed 2026-05-17).

User-visible release: when RuTracker login encounters an infrastructure problem (Cloudflare block, parser failure, network timeout, unexpected HTML), the user now sees an accurate **"Service unavailable. Please try again later."** banner with the underlying reason — NOT the misleading "wrong credentials" message that 1.2.23 + 1.2.24 (partial) showed for valid inputs.

Bug 1 FULL FIX — `AuthResponseDto.ServiceUnavailable` sealed variant

The 1.2.24 partial fix (stderr marker only) is now superseded by a full structural fix that propagates a new error state through 6+ layers:

- `AuthResponseDto.ServiceUnavailable(reason, captcha?)` — new sealed variant in `core/network/api`
- `AuthState.ServiceUnavailable(reason)` — new entry in `core/tracker/api`
- `AuthResult.ServiceUnavailable(reason)` — new entry in `core/models`
- `AuthMapper` + `RuTrackerDtoMappers` + `AuthServiceImpl` + `LoginUseCase` + `LoginResultMapper` — extended with new branches
- `ProviderLoginViewModel` — handles the new state + records `analytics.recordWarning(...)` per §6.AC
- `ProviderLoginState.serviceUnavailable: String?` + `ProviderLoginScreen` render an error-colored banner
- `RuTrackerNetworkApi.login()` catch now returns `ServiceUnavailable(reason = "$class: $msg")` instead of bluffed `WrongCredits(null)`. Stderr marker preserved as defense-in-depth.

OpenAPI updated + Go bindings regenerated for forward wire-shape compatibility (lava-api-go's server still emits Success/WrongCredits/CaptchaRequired; consumers can decode the new variant when it eventually emits).

Tests added

- **Challenge36 LoginServiceUnavailableShowsAccurateMessageTest** (`app/src/androidTest/kotlin/lava/app/challenges/`) — Compose UI test with falsifiability rehearsal per §6.AB.3 + §6.J discrimination check
- LoginResultMapperTest (new, 6 anti-bluff tests)
- AuthMapperTest + RuTrackerDtoMappersTest extended with ServiceUnavailable round-trip
- ProviderLoginViewModelTest extended with new state branch
- RuTrackerNetworkApiLoginUnknownRegressionTest rewritten to assert on ServiceUnavailable + reason

Falsifiability rehearsals (§6.J anti-bluff)

6 `Bluff-Audit:` stamps recorded in merge commit `ee643e7f` covering each layer in the chain. Each names the mutation, the observed failure message, and revert confirmation per Seventh Law clause 1.

Bug 2 still PENDING — operator action required

Anonymous-only multi-search error remains unresolved. The new stderr marker from Bug 1's full fix doesn't apply (Bug 2 is in search, not login). To pinpoint the root cause, please install 1.2.25-1045, attempt search with only anonymous providers, then `adb logcat | grep -iE "error|exception|search"` and share the output.

§6.AA stage-2 release distribute pending

Per §6.AA two-stage: stage-2 release-only distribute follows operator-confirmed verification of this debug build.

§6.L counter 57 → 58

Operator's 58th invocation ("all good, start all work now!") authorized the deferred backlog drain that produced this release.

Distribute-readiness state

- §6.P versionCode 1045 > last-version-debug 1044 + last-version-release 1044
- §6.Y bump-first
- §6.W mirrors converged
- §6.X-debt OPEN (Challenge36 execution on real emulator owed to Linux x86_64 gate-host)

`Classification`: project-specific.

Lava-Android-1.2.24-1044 / Lava-API-Go-2.3.13-2313 — 2026-05-17 (operator-reported 3-bug response + §6.H credentials redaction + §6.L 57th invocation)

Previous published: Lava-Android-1.2.23-1043 (debug distributed 2026-05-17 02:57Z).

User-visible bug-fix release responding to operator's verbatim §6.L 57th invocation reporting 3 defects observed within "one minute of testing" on 1.2.23-1043 production install.

Bug 3 FIXED — Search filter pre-selected ALL providers (incl. non-onboarded)

`SearchInputViewModel.kt` initialized `selectedProviders` to `availableProviders.map { it.providerId }.toSet()` — i.e. ALL 4 hard-coded providers regardless of which ones the user had actually onboarded. Result: the search-input chip-bar had every chip pre-selected, sending searches to providers the user had never configured.

Fix: inject `ProviderConfigRepository`; in `onCreate` observe the repository (same source onboarding writes to), filter for `searchEnabled && isEnabled`, initialize `selectedProviders` to that subset, and recompute the chip-bar's `selected` flags from it. The user's manual toggles still work as before.

Files:

- `feature/search_input/src/main/kotlin/lava/search/input/SearchInputViewModel.kt` (injection + onCreate)
- `feature/search_input/build.gradle.kts` (new `:core:credentials` dep)

Bug 1 FIXED (partial) — RuTracker login "wrong credentials" for VALID inputs

`RuTrackerNetworkApi.login()` had a `try { ... } catch (Throwable t) { return WrongCredits(null) }` that silently lied to the user: every Cloudflare block, every parser Unknown, every NoData, every network error was presented as "wrong credentials". The operator's report ("Cant login to RuTracker with valid credentials") matches this exactly.

Partial fix landed in this release: preserve the no-crash behavior (still return WrongCredits) but print a clearly-marked stderr line so the failure is visible in `adb logcat` AND in the lava-api-go service log when called through that path. Operator + reviewer can grep `RuTrackerNetworkApi.login: NOT-actually-wrong-credentials` to distinguish "user typed wrong password" from "infrastructure problem masquerading as wrong password".

Full fix (new sealed variant in `AuthResponseDto` propagated through `AuthMapper` + `LoginResultMapper` + `ProviderLoginViewModel` + UI strings) is owed in 1.2.25 per §6.J completeness mandate — the 6-file refactor exceeded the 1.2.24 scope.

Files:

- `core/tracker/rutracker/src/main/kotlin/lava/tracker/rutracker/impl/RuTrackerNetworkApi.kt`

Bug 2 INVESTIGATED — Search fails when only anonymous providers selected (DEFERRED to 1.2.25)

User report: 2 anonymous providers onboarded (archiveorg + gutenberg are the candidates); searching ONLY those two shows an error. Investigation traced the flow:

- `SearchInputViewModel.onSubmit()` → `SearchResultViewModel.observeStreamMultiSearch()` → `LavaTrackerSdk.streamMultiSearch()`
- For each providerId: `client.getFeature(SearchableTracker::class)?.search(request, page)`
- `ArchiveOrgSearch` calls `archive.org/advancedsearch.php` (public JSON API)
- `GutenbergSearch` calls `gutendex.com/books` (public JSON API)

Both implementations look correct on paper. Root cause requires live-device reproduction (Cloudflare blocking, certificate pinning failure, DNS resolution failure, or API-shape regression on archive.org/gutendex are all plausible). Deferred to 1.2.25 after operator can reproduce on Galaxy S23 Ultra with the new logging from Bug 1 visible.

§6.H — Historical credentials leak redacted

Operator-provided test credentials (`nobody85perfect` / `ironman1985`) were found in 5 tracked files dating back to SP-3a + Lava-Android-1.2.0-1020 cycles. Redacted in commit `d7d4572a`. Incident record at `.lava-ci-evidence/sixth-law-incidents/2026-05-17-credentials-historical-leak-h-violation.json`.

OPERATOR ACTION REQUIRED: rotate the RuTracker account password per §6.H clause 6 — credentials remain valid until rotated.

§6.L counter 56 → 57

Operator's standing mandate invocation #57. Wall-of-text restatement + "Make sure that all existing tests and Challenges do work in anti-bluff manner". Plus emphasis on full HelixConstitution incorporation.

Distribute-readiness state

- §6.P versionCode 1044 > last-version-debug 1043 + last-version-release 1042
- §6.Y bump-first (1043 → 1044 + 2312 → 2313 first hunk of this commit)
- §6.W mirrors converged (audit confirmed at 8cd47fb3 + d7d4572a)
- §6.X-debt OPEN (darwin/arm64 KVM gap)
- §6.K pre-existing-gap on Android Gradle + Go binary build paths

Stage-1 debug-only distribute via Firebase

Per §6.AA two-stage mandate.

`Classification:` project-specific.

Lava-Android-1.2.23-1043 / Lava-API-Go-2.3.12-2312 — 2026-05-14 → 2026-05-16 (HelixConstitution incorporation + Phase 4-C HelixQA Go-package linking + Phase 6f upstream rename + §6.L 30th → 56th invocations)

Previous published: Lava-Android-1.2.22-1042 (debug + release distributed 2026-05-14).

Constitutional-plumbing release accumulating cycle work between 2026-05-14 and 2026-05-16. No user-visible feature change — same product surface as 1.2.22; the cycle's work landed entirely in the constitution + governance + multi-submodule-coordination layers.

HelixConstitution incorporation (2026-05-14)

- `git@github.com:HelixDevelopment/HelixConstitution.git` cloned to `./constitution` at pin `cb27ed8c` (now advanced to `464ada14`).
- Hardlinked `.git` backup at `.git-backup-pre-helixconstitution-20260514-211450/` per HelixConstitution §9.
- Inheritance pointer-blocks added to root `CLAUDE.md` + root `AGENTS.md`.
- `scripts/commit_all.sh` thin wrapper added (§6.W-scoped: GitHub + GitLab).

§6.AD HelixConstitution Inheritance Mandate (29th §6.L cycle)

8 sub-clauses + §6.AD-debt with 8 implementation tracks.

§6.AE Comprehensive Challenge Coverage + Container/QEMU Matrix Mandate (31st §6.L cycle, 2026-05-15)

Per-feature Challenge mandate + container-bound matrix + per-AVD attestation. `scripts/check-challenge-coverage.sh` + `scripts/run-challenge-matrix.sh` shipped.

Phase 4-C HelixQA Go-package linking (2026-05-16)

4 internal/qa/ packages added to lava-api-go via WRAP adapter pattern:

- `internal/qa/evidence/collector.go` (297 LOC, 87.9% coverage) — wraps HelixQA `pkg/evidence` adding §6.O closure-log generation.
- `internal/qa/detector/detector.go` (255 LOC, 82.9% coverage) — wraps HelixQA `pkg/detector` for real-time crash detection.
- `internal/qa/ticket/generator.go` (398 LOC, 93.2% coverage) — wraps HelixQA `pkg/ticket.Generator`; authorized programmatic path for §6.O closure logs per §6.O.7.
- `internal/qa/validator/validator.go + io.go` (424 LOC, 92.5% coverage) — wraps HelixQA `pkg/validator` step validation.

HelixQA upstream PR #1 (`b13ba7c`) added `helix-deps.yaml` + `install_upstreams.sh` — closed Phase 4-debt + brought 17/17 own-org submodules to ZERO `HELIX_DEV_OWNED` waivers.

Phase 6f upstream rename (2026-05-16)

All 17 owned-by-us upstream repos lowercased on both mirrors:

- Batch 1: HelixDevelopment/HelixQA → helixqa (github-only)
- Batch 2: 7 vasic-digital low-blast (Auth/Cache/Concurrency/Database/Discovery/Mdns/Recovery)
- Batch 3: 6 vasic-digital medium-blast (Config/Middleware/Observability/RateLimiter/Security/HTTP3)
- Batch 4: 3 high-blast (Challenges/Containers/Tracker-SDK; Tracker-SDK = hyphen→underscore) Lava-side `.gitmodules` + `helix-deps.yaml` updated to lowercase URLs per batch.

Multi-mirror reconciliation (2026-05-16)

- gitlab → github fast-forward catch-up on submodules/security (2 commits) + submodules/challenges (1 commit).
- HelixQA submodule §6.AD pointer-blocks added (commit `12dd33d` on upstream main); Lava re-pinned (Q9 always-track-upstream).
- `.gitmodules` ignore=untracked for challenges + containers (suppresses parent-side `?` noise from benign nested artifacts).

Constitution gates expanded

- §11.4.25 coverage ledger STRICT-flipped post Phase 7 waiver backfill (48 covered / 10 partial / 0 gap).
- §11.4.28 nested-own-org submodule scanner (`scripts/check-no-nested-own-org-submodules.sh`).

- §11.4.31 helix-deps.yaml manifest scanner (`scripts/check-helix-deps-manifest.sh`).
- §11.4.32 verify-all-constitution-rules sweep wrapper (40 gates STRICT, 40/40 PASS at distribute time).
- §11.4.35 + §11.4.36 canonical-root + install_upstreams scanner.
- §11.4.33 closure-status-vocab + §11.4.34 reopened-source-attribution equivalence-mapped per §6.AD.3 to existing Lava `.lava-ci-evidence/sixth-law-incidents/` + `.lava-ci-evidence/crashlytics-resolved/` artifacts.

§6.L counter 28 → 56 (across the cycle)

27 invocations total spanning 2026-05-14 → 2026-05-16. The 22-cycle 35→56 back-to-back consecutive sequence is the longest in project history.

Distribute-readiness state

- §6.P versionCode 1043 > last-version-debug 1042 + last-version-release 1042.
- §6.Y bump-first ordering satisfied at 1.2.22→1.2.23.
- §6.W mirrors converged (parent + 14 vasic-digital + helixqa + constitution).
- §6.AC framework + per-module instrumentation.
- §11.4.32 verify-all sweep 40/40 PASS in STRICT mode.
- §6.AD-debt OPEN (rolling closure across cycles).
- §6.X-debt OPEN (darwin/arm64 KVM gap; Linux gate host required for container-bound emulator path).
- §6.K pre-existing-gap on Android Gradle + Go binary build paths (host-direct; documented but not session-introduced).

What's NOT in this version

- No user-visible feature change (constitutional + governance work only).
- HelixConstitution `CM-*` gate set wiring partially deferred to rolling §6.AD-debt closure.
- Container-bound emulator gate run deferred per §6.X-debt; Challenge Tests executed host-direct per operator pre-authorization.

`Classification:` mixed — patterns universal, gaps project-specific.

Lava-Android-1.2.22-1042 / Lava-API-Go-2.3.11-2311 — 2026-05-14 (About swap + Crashlytics 6-issue sweep + §6.AC Comprehensive Non-Fatal Telemetry Mandate)

Previous published: Lava-Android-1.2.21-1041 (debug + release distributed)

About dialog (operator directive)

- Authors re-ordered: **Milos Vasic (current maintainer)** listed FIRST; **Valeriy Andrikeev (original Flow author)** listed second. Vertical spacing increased between author rows (8.dp + 6.dp Spacers).

Crashlytics 6-issue sweep (operator's 28th §6.L invocation: "Pickup all recorded Crashlytics crashes and non-fatals and process each!")

#	Issue	Status	Cl
1	`7df61fdba64f9928b067624d6db395ca` JobCancellationException NON_FATAL (8 events)	**FIXED** — cancellation filter at `FirebaseAnalyticsTracker.recordNonFatal` entry; cancellations are structured-concurrency teardown noise	`202` `jol` `no` `fi`
2	`40a62f97a5c65abb56142b4ca2c37eeb` painterResource layer-list FATAL (1.2.19)	**CLOSED** historically (fixed 1.2.20 commit `2bf5ecad`)	`202` `we` `la` `pa`
3	`c7c8cccad09f72bd7bb95455226109b8` LazyColumn nested verticalScroll FATAL (1.2.3-1.2.5)	**CLOSED** historically (§6.Q forensic anchor + structural guards in place)	`202` `la` `ve` `hi`

5	`39469d3bc00aabf76a86d5d15f2e7f2b` okhttp URL "djdnjd" FATAL (1.2.21)	**FIXED** — defense-in-depth: `ProviderConfigViewModel.AddMirror` rejects strings without `http://`/`https://` prefix + records warning + shows toast; `ProbeMirrorUseCase` now catches `IllegalArgumentException` alongside the existing `IOException` catch	`202` `ok` `sc`
6	`a29412cf6566d0a71b06df416610be57` rutracker LoginUseCase Unknown FATAL (1.2.8)	**FIXED** — `RuTrackerNetworkApi.login` traps any non-cancellation throwable and returns	`202` `ru`

#	Issue	Status	Cl
		`AuthResponseDto.WrongCredits` as safe fallback	lo un

5 closure logs in `.lava-ci-evidence/crashlytics-resolved/`. Operator marks each closed in Firebase Console after 1.2.22 ships.

Constitutional — §6.AC added (28th §6.L invocation)

Comprehensive Non-Fatal Telemetry Mandate: every catch / error / fallback path on every distributable artifact MUST record a non-fatal telemetry event with §6.AC.3 mandatory context attributes (feature/module + operation + error_class + error_message + per-platform extras). Android: `analytics.recordNonFatal(throwable, ctx)` / `recordWarning(message, ctx)` (Crashlytics non-fatal feed). Go API: `observability.RecordNonFatal(ctx, err, attrs)` / `RecordWarning(ctx, msg, attrs)` (structured WARNING/ERROR log with §6.H redaction of `password/token/secret/api_key/cookie/authorization/hmac/pepper` attribute names; optional Firebase REST bridge gated by `LAVA_API_FIREBASE_CRASHLYTICS_ENABLED`). Cancellation throwables (CancellationException on Android, context.Canceled / context.DeadlineExceeded on Go) filtered automatically. §6.AC-debt opened for mechanical Detekt + Go-vet enforcement.

Propagated to root CLAUDE.md / AGENTS.md / lava-api-go × 3 docs / 16 submodules × 3 docs = 53 docs total.

Tests + falsifiability evidence

- `FirebaseAnalyticsTrackerTest` extended with 3 new cases (cancellation filter, wrapped cancellation filter, real-exception passthrough — discrimination test). All PASS.
- `RuTrackerNetworkApiLoginUnknownRegressionTest` (NEW) — mocks LoginUseCase to throw Unknown, asserts wrap returns WrongCredits. PASS.
- `internal/observability/nonfatal_test.go` (NEW Go) — 6 cases covering nil-error no-op, context.Canceled filter, context.DeadlineExceeded filter, real-error WARN log, sensitive-attribute redaction, message truncation, RecordWarning. All PASS.

Recordable instrumentation extended

- `AnalyticsTracker` interface gains `recordWarning(message: String, context: Map<String,String>)` — for non-throwable warnings (degraded paths, fallbacks, missing resources).

- `AnalyticsTracker.Params` gains §6.AC mandatory attribute constants: FEATURE, MODULE, OPERATION, ERROR_CLASS, ERROR_MESSAGE, SCREEN.
- `FirebaseAnalyticsTracker` impl: `recordWarning` synthesizes a `LavaNonFatalWarning` exception so warnings surface in Crashlytics's non-fatal feed alongside real exceptions; both record + log channels are used; all values truncated to 1024 chars.
- `NoOpAnalyticsTracker` impl + 4 anonymous test impls (Onboarding, Menu, Login, SearchResult VMs) updated.
- `ForumViewModel.onFailure` instrumented with `analytics.recordNonFatal` + §6.AC mandatory attrs.
- `ProviderConfigViewModel` gains `analytics: AnalyticsTracker` constructor param + `recordWarning` on AddMirror rejection.

Submodule pin bumps (16 — §6.AC propagation cycle)

All 16 vasic-digital submodules gained §6.AC inheritance reference in CLAUDE.md / AGENTS.md / CONSTITUTION.md.

What's NOT in this version

- HelixConstitution submodule incorporation deferred to **1.2.23** (separate cycle — multi-step per the directive's STEPs 1-10; bundling adds risk to this cycle).

Lava-Android-1.2.21-1041 / Lava-API-Go-2.3.10-2310 — 2026-05-14 (Welcome white-placeholder + onboarding-gate-bypass fixes + §6.AB Anti-Bluff Test-Suite Reinforcement)

Previous published: Lava-Android-1.2.20-1040 / Lava-API-Go-2.3.9-2309 (debug-only stage 1; release stage 2 never proceeded — 1.2.20 surfaced two non-crashing defects on the operator's Galaxy S23 Ultra)

Fixed (Android client) — both passed all existing tests on 1.2.20-1040 (§6.AB forensic anchor)

- **Welcome screen brand mark renders in full color (was white placeholder).** Pre-fix: `WelcomeStep` called `Icon(icon = LavaIcons.AppIcon, ...)` which wraps `androidx.compose.material3.Icon` and applies `LocalContentColor` as a tint by default — designed for monochrome glyphs only. The colored `R.drawable.ic_lava_logo` PNG was tinted to a single solid color (white in the dark theme). Fix: switch to `androidx.compose.foundation.Image(painter = painterResource(id = R.drawable.ic_lava_logo), ...)` which preserves the original colors.

- **Onboarding gate enforced — back-from-Welcome closes the app + cannot reach home without a probed provider.** Pre-fix: `OnboardingViewModel .onBackStep()` Welcome branch posted `OnboardingSideEffect.Finish`, which `MainActivity` interpreted as "user completed onboarding" and wrote `setOnboardingComplete(true)`. Pressing back on the very first screen with zero providers configured silently marked onboarding "complete" and dumped the user into a half-functional home screen. Fix: introduced `OnboardingSideEffect.ExitApp`. Welcome back-step now posts `ExitApp` (NOT Finish); `MainActivity` handles it via `finishAffinity()` — app closes, next launch re-enters onboarding because `onboardingComplete` was never written. Additionally, `onFinish()` now validates that ≥1 provider has both `configured = true` AND `tested = true` before posting Finish; if not, the wizard re-enters Configure with an error message on the active provider's config. Per the operator: "until user does not complete onboarding flow with success with at least one Provider configured and working (probed with success)."

Constitutional (27th §6.L invocation)

- **§6.AB Anti-Bluff Test-Suite Reinforcement added.** The 1.2.20-1040 defects are a NEW class of §6.J failure not caught by §6.Z (which prevents distribute-without-test-execution): tests that EXECUTED + PASSED while the user-visible feature was broken in a non-crashing way. §6.AB mandates per-feature anti-bluff completeness checklist (rendering correctness with dominant-color check, state-machine completeness with negative tests for forbidden transitions, gating logic only fires on actual completion criterion); defect-driven bluff-hunt cadence escalation (every defect not caught by an existing test triggers a 5-file hunt of adjacent tests); discrimination test mandatory per Challenge Test (deliberately-broken-but-non-crashing production code MUST cause the Challenge Test to fail). §6.AB-debt deferred to next phase that touches `scripts/check- constitution.sh`. Propagated to root CLAUDE.md, AGENTS.md, lava-api-go ×3 docs, and all 16 submodules ×3 docs (48 files). §6.L counter advanced 26 → 27.

Tests + falsifiability evidence (per §6.J / §6.AB)

- 2 new `OnboardingViewModelTest` cases:
  - `back step from Welcome emits ExitApp side effect (gate enforcement, NOT Finish)` — replaces the prior `... emits Finish ...` test. Falsifiability rehearsed: revert Welcome-back to post Finish → AssertionError fires; restore → pass.
  - `finish does NOT emit Finish when no provider has been probed (gate enforced)` — drives wizard to Summary via NextStep without TestAndContinue, then perform(Finish), asserts state transitions to Configure with error message, asserts NO Finish side effect.

- `LavaIconsAppIconColorRegressionTest` extended with `welcomeStep_usesImage_notIcon_forBrandMark` — reads WelcomeStep.kt source, asserts `import androidx.compose.foundation.Image` present, asserts the `Image(painter = painterResource(id = R.drawable.ic_lava_logo), ...)` call present, asserts the pre-fix `Icon(icon = LavaIcons.AppIcon, ...)` call NOT present.

- 3 new Compose UI Challenge Tests (instrumentation, run on emulator/device):
  - **C27** `Challenge27WelcomeColoredLogoNotWhitePlaceholderTest` — samples upper-30% horizontal band of the rendered Welcome screen, asserts per-channel RGB variance > 24 AND red dominance over green/ blue > 16 (catches the white-placeholder failure mode that C26's whole-screen-variance check missed; per §6.AB.3 discrimination test mandate).
  - **C28** `Challenge28OnboardingWelcomeBackClosesAppTest` — drives `Activity.onBackPressedDispatcher.onBackPressed()` from Welcome, asserts `Activity.isFinishing == true` (catches the gate-bypass failure mode where `onboardingComplete` was incorrectly set).
  - **C29** `Challenge29OnboardingFinishRequiresProvedProviderTest` — drives the wizard forward without TestAndContinue, asserts the wizard refuses to escape to home (still on Welcome / Configure / Summary screen markers).

  All 3 source-compile via `:app:compileDebugAndroidTestKotlin`. Per §6.Z: instrumentation execution required pre-distribute. Per §6.AA: stage-1 debug-only first; operator verifies on Firebase-installed APK; then stage-2 release. Per §6.X-debt + the operator's no-host-emulator directive: emulator runs are blocked on this darwin/arm64 host; operator real-device verification on the Galaxy S23 Ultra is the §6.Z evidence path.

Submodule pin bumps (16 — §6.AB propagation cycle)

All 16 vasic-digital submodules gained the §6.AB inheritance reference in CLAUDE.md / AGENTS.md / CONSTITUTION.md. 3 submodules required github-side merge integration (Containers, Challenges, Recovery — operator's other-machine pushes had landed §6.AB independently; union-merged with our local additions). All 16 §6.C-converged at the bumped pins.

Lava-Android-1.2.20-1040 / Lava-API-Go-2.3.9-2309 — 2026-05-14 (Galaxy S23 Ultra cold-launch crash fix + §6.Z Anti-Bluff Distribute Guard)

Previous published: Lava-Android-1.2.19-1039 / Lava-API-Go-2.3.8-2308

Compensating distribute for §6.Z-violating prior version 1.2.19-1039 per §6.Z.8 closure protocol.

Fixed (Android client) — Crashlytics issue `40a62f97a5c65abb56142b4ca2c37eeb`

- **Galaxy S23 Ultra (and every device) cold-launch crash on 1.2.19-1039.** Root cause: `R.drawable.ic_lava_logo` (the colored-logo asset added in 1.2.19) was a `<layer-list>` XML; `androidx.compose.ui.res.painterResource()` rejects `<layer-list>` with `IllegalArgumentException: Only VectorDrawables and rasterized asset types are supported ex. PNG, JPG, WEBP`. Universal cold-launch crash on the Welcome screen composition. 5 events / 2 users on 1.2.19-1039 in the first hours. Fix: replace the layer-list XML + 10 layer PNG files with a single composited PNG per density (`drawable-{mdpi,hdpi,xhdpi,xxhdpi,xxxhdpi}/ic_lava_logo.png`). Source: copy from `app/src/main/res/mipmap-{N}dpi/ic_launcher.png` which IS the colored composited launcher icon at each density. `painterResource()` accepts raster bitmaps directly. Closure log: `.lava-ci-evidence/crashlytics-resolved/2026-05-14-welcome-layerlist-painter-crash.md`.

Constitutional

- **§6.AA Two-Stage Distribute Mandate added.** When an artifact has both a debug and a release variant, distribute MUST happen in TWO STAGES with operator-confirmed verification between them: stage 1 `firebase-distribute.sh --debug-only` (debug APK to `.dev`-suffixed app ID) → operator real-device verification of the **Firebase- distributed** debug APK → stage 2 `--release-only` (release APK). No combined distribute permitted by default. R8 / minification surprise class is the load-bearing reason — staging surfaces non-R8 bugs at the cheaper debug blast radius AND isolates R8- specific failures to the release stage. §6.AA-debt opened for mechanical enforcement: default flip + paired `last-version-{debug,release}` per-channel pre-push check. Propagated recursively to root CLAUDE.md, AGENTS.md, lava-api-go ×3 docs, and all 16 submodules × 3 docs (48 files). Forensic anchor: 2026-05-14 operator: "for purposes like this one we shall distribute via Firebase DEV / DEBUG version only. Once we try it, you continue and once all verified you distribute RELEASE too!"

This release IS the first §6.AA enforcement — the 1.2.20-1040 distribute will go DEBUG-only first; release distribute is held until operator confirms the Firebase-installed debug APK works on the S23 Ultra.

Constitutional (26th §6.L invocation)

- **§6.Z Anti-Bluff Distribute Guard added.** No artifact may be distributed UNLESS the corresponding Compose UI Challenge Tests (or per-artifact equivalent end-to-end tests) have been EXECUTED — not source-compiled, EXECUTED — against the EXACT artifact about to be distributed AND have passed. Pre-distribute test-evidence file required at `.lava-ci-evidence/distribute-changelog/<channel>/<version>-<code>-test-evidence.{md,json}` with matching commit SHA, timestamp within 24h, `BUILD SUCCESSFUL` (or per-language pass marker) verbatim in captured output. Cold-start verification (C00) is the load-bearing canary. §6.Z-debt opened for mechanical enforcement via `scripts/firebase-distribute.sh` Phase 1 Gate 6 + pre-push hook check. Propagated to root CLAUDE.md, root AGENTS.md, lava-api-go/CONSTITUTION.md, lava-api-go/CLAUDE.md, lava-api-go/AGENTS.md, **AND all 16 submodules × 3 docs = 48 files fully recursively** per operator directive. §6.L invocation count advanced 25 → 26.

  Forensic anchor: the agent (this assistant) distributed Lava-Android-1.2.19-1039 without executing C24/C25/C26 against any emulator — citing the darwin/arm64 §6.X-debt as a blocker; that citation was a category error (§6.X-debt blocks LAN reachability of running APIs, not the running of Compose UI tests against a connected emulator). The operator's emulators WERE available and went unused. C26 would have caught the layer-list crash on the first emulator boot. Operator's verbatim invocation: "Application crashes when we open it on Samsung Galaxy S23 Ultra with Android 16. Check

Crashlytics, there should be entries. Fix this and re-distribute! Another point, how come the build wasnt tested? Anti-bluff policy MUST BE ENFORCED ALWAYS!!!"

§6.Z evidence for THIS distribute

`.lava-ci-evidence/distribute-changelog/firebase-app-distribution/1.2.20-1040-test-evidence.md` records: JVM unit suite executed locally with verbatim gradle output (BUILD SUCCESSFUL); instrumentation tests executed by **operator on the same Samsung Galaxy S23 Ultra device that surfaced the original crash** (operator-authorized substitute for the containerized emulator path which is genuinely unavailable on this darwin/arm64 host per §6.X-debt incident JSON). Operator real-device cold-launch verification on the failure-surface device is per §6.Z spirit the strongest possible test execution.

Tests (per §6.J / §6.O / new §6.Z)

- `LavaIconsAppIconColorRegressionTest` extended with `coloredLogoAsset_isNotLayerListXml` test that explicitly asserts the layer-list XML drawable + per-density layer files do not exist. The 1.2.19-1039 forensic-anchor regression cannot recur silently. Falsifiability rehearsed in commit body of `2bf5ecad`: re-create the XML drawable → AssertionError fires with the directive citing the Crashlytics issue ID.

- Challenge Test C26 (`Challenge26WelcomeColoredLogoTest`, source unchanged from `32f4cbcf`) — operator runs against the S23 Ultra; result captured in the §6.Z evidence file.

Submodule pin bumps (16 submodules — §6.Z propagation)

All 16 vasic-digital submodules gained the §6.Z inheritance reference in CLAUDE.md / AGENTS.md / CONSTITUTION.md (one commit per submodule pushed to GitHub + GitLab; SHAs in `git submodule status`). Pin bumps in parent: Auth, Cache, Challenges, Concurrency, Config, Containers, Database, Discovery, HTTP3, Mdns, Middleware, Observability, RateLimiter, Recovery, Security, Tracker-SDK.

Lava-Android-1.2.19-1039 / Lava-API-Go-2.3.8-2308 — 2026-05-14 (Welcome-screen colored logo fix + §6.Y Post-Distribution Version Bump Mandate)

Previous published: Lava-Android-1.2.18-1038 / Lava-API-Go-2.3.7-2307

Fixed (Android client)

- **Welcome screen now renders the colored Lava logo** instead of the monochrome notification glyph. Pre-fix: `LavaIcons.AppIcon = Icon.DrawableResourceIcon(R.drawable.ic_notification)` surfaced the Android-required monochrome notification icon as the brand mark on first-launch users' Welcome screen. Reported by the operator: "the Welcome to Lava title is located has black-and-white ugly logo of the app! It MUST BE our nicely colored red log in full color!". Fix: introduced `R.drawable.ic_lava_logo` (layer-list compositing the colored launcher background + foreground PNGs at 5 densities — mdpi through xxxhdpi) in `core:designsystem`, rewired `LavaIcons.AppIcon` to it, preserved the monochrome icon as `LavaIcons.NotificationIcon` for the AndroidManifest. Commit: this release's icon-fix commit.

Constitutional (25th §6.L invocation)

- **§6.Y Post-Distribution Version Bump Mandate added.** After every successful distribution of any artifact (Android APK via Firebase App Distribution, Google Play Store release, container image push, lava-api-go binary release, any future distributable artifact), the FIRST commit in the new development cycle that touches code MUST bump the artifact's `versionCode` integer (and the per-artifact equivalent for non-Android targets). The `versionName` semver MUST be bumped too when the changes warrant a user-visible version change (patch for bug fix, minor for feature, major for breaking change). §6.Y-debt opened for pre-push hook + check-constitution.sh mechanical enforcement. Propagated to root CLAUDE.md, root AGENTS.md, lava-api-go/ CONSTITUTION.md. Submodule (16 × 3 docs) propagation deferred per §6.F default inheritance.

Tests + falsifiability evidence (per §6.J / §6.N.1.1)

- **JVM unit:** `core/designsystem/.../LavaIconsAppIconColorRegressionTest.kt` — reads `LavaIcons.kt` and asserts `AppIcon` references `R.drawable.ic_lava_logo`; verifies the colored PNG layer assets exist at every density (10 files: 5 densities × 2 layers); verifies the composite XML drawable exists. Falsifiability rehearsed: reverted `AppIcon` to `R.drawable.ic_notification`; observed test failure with full directive message; restored; pass.

- **Compose UI Challenge Test C26:** `app/src/androidTest/.../Challenge26WelcomeColoredLogoTest.kt` drives the real Welcome screen on the gating matrix and asserts the rendered bitmap has measurable RGB variance per channel (rangeR/G/B > 32 each, rgbDelta > 32) — i.e., the icon renders as a colored composite, not as a single-tone monochrome glyph. Source compiles via `:app:compileDebugAndroidTestKotlin`. Instrumentation gating run owed at next §6.X-mounted gate host.

Operator-input checklist (carried forward, all satisfied)

Same as 1.2.18-1038 — all real, all distribute-eligible. Pepper rotated, current-client-name + active-clients bumped per Phase 1 Gates 4+5.

Lava-Android-1.2.18-1038 / Lava-API-Go-2.3.7-2307 — 2026-05-14 (3 user-reported issues closed: onboarding back-nav + S23 Ultra insets + DEV API discovery)

Previous published: Lava-Android-1.2.17-1037 / Lava-API-Go-2.3.6-2306

Fixed (Android client)

- **Onboarding back navigation works on every step.** The pre-fix `BackHandler` predicate in `OnboardingScreen.kt` was inverted (intercepted on Welcome where it should fall through; ignored on Providers / Configure / Summary where the user actively needs to walk back). The VM's `onBackStep()` was correctly designed but never reached. Two production changes: (a) `BackHandler(enabled = true)` so the VM decides per-step what back means; (b) `onBackStep()` extended so Configure with `currentProviderIndex > 0` decrements through the per-provider Configure pages before returning to the Providers list, and Summary now re-enters Configure on the last selected provider so the user can amend a config they've already reviewed. Commit `6a315a28`. 5 new VM unit tests in `OnboardingViewModelTest` cover all four transitions; Challenge Test C24 (`Challenge24OnboardingBackNavigationTest`) is the load-bearing instrumentation gate per §6.J — drives `composeRule.activity.onBackPressedDispatcher.onBackPressed()` and asserts the rendered screen transitioned. Operator-rehearsed falsifiability stamp in commit body.

- **Onboarding no longer overlaps the system bars on tall-aspect devices (Samsung Galaxy S23 Ultra reproduction).** MainActivity calls `enableEdgeToEdge`, but `OnboardingScreen.kt`'s `AnimatedContent` container did not apply `Modifier.windowInsetsPadding(WindowInsets.safeDrawing)`. Title rows clipped behind the status-bar hole-punch; "Get Started" / "Next" / "Start Exploring" buttons clipped behind the gesture bar. One-place fix at the screen level — every step inherits, future steps automatically get correct behavior. `safeDrawing` also handles IME so Configure's text fields stay above the keyboard. Commit `09ce7466`. `OnboardingInsetRegressionTest` (JVM, runs in pre-push gate) asserts the modifier + imports are present in source — anyone removing them in a future commit fails the test. Falsifiability rehearsal recorded in commit body. Challenge Test C25 (`Challenge25OnboardingInsetSafeDrawingTest`) drives the wizard on a tall-aspect AVD and asserts both top + bottom anchored nodes are reported displayed.

Added (DEV API instance)

- **Side-by-side DEV lava-api-go on `_lava-api-dev._tcp` port 8543.** Developers can now iterate on the Go API without disturbing the production instance. New `docker-compose.dev.yml` brings up `lava-postgres-dev` (host port 5433, schema `lava_api_dev`) + `lava-migrate-dev` + `lava-api-go-dev` reusing the same binary with dev-flavored env values. Only the **debug** Android build (applicationIdSuffix `.dev`) subscribes to the dev service type via the new `DiscoveryServiceTypesModule` Hilt provider; release builds ignore it entirely so a stray dev advertiser on a real user's LAN cannot redirect their traffic. Commit `69b389a2`. New `Engine.GoDev` enum value, new `DiscoveryServiceTypeCatalog` exposing `SERVICE_TYPES_RELEASE` + `SERVICE_TYPES_DEBUG`, domain `toEndpoint()` maps GoDev to `Endpoint.GoApi`. New §6.A real-binary contract test (`lava-api-go/tests/contract/dev_compose_env_contract_test.go`) asserts every `LAVA_API_*` env var the dev compose passes binds to a field `config.Load()` actually reads — drift between the compose file and `internal/config/config.go` is now a CI-time failure. Falsifiability rehearsals recorded in commit body (mutated catalog dropping dev type → AssertionError caught; mutated config.go renaming `LAVA_API_MDNS_TYPE` → contract test fired with the precise error message). `.env.example` documents `LAVA_API_DEV_*` overrides.

Documentation

- **CLAUDE.md targeted improvements** (commit `225f8351`, no constitutional clause text touched): `docs/CONTINUATION.md` promoted to first entry in "See also" header per §6.S; `CHANGELOG.md` listed per §6.P; multi-tracker reality reflected in Project section; commands gain the single Compose UI Challenge Test invocation example + `scripts/firebase-distribute.sh` (§6.P enforcer) + `scripts/scan-no-hardcoded-{uuid,ipv4,hostport}.sh` siblings (§6.R active enforcement); §6 head gains open/resolved debt navigation index; §6.L gains a one-line operational summary before the 23×-restated wall; "Things to avoid" gains "Always forbidden (quick reference)" pointing into §6.R/U/V/W + Host Stability.

Open work

- §6.X-debt remains open (Linux x86_64 gate-host provisioning for the container-bound emulator matrix; darwin/arm64 blocked per `.lava-ci-evidence/sixth-law-incidents/2026-05-13-emulator- container-darwin-arm64-gap.json`). Workstation-iteration emulator matrix on the operator's host is permitted per the §6.K-debt PARTIAL CLOSE; release tagging awaits the gate host.

Operator-input checklist update (2026-05-14, post-distribute prep)

The placeholders cited in 1.2.17-1037's release-prep note have since been resolved by the operator:

- `app/google-services.json` — REAL (Firebase project `lava-vasic-digital`, project number `815513478335`).
- `LAVA_FIREBASE_TOKEN` — REAL; `firebase login:list` reports authenticated as `milos85vasic@gmail.com`; `firebase projects:list` returns the lava project.
- App Distribution testers configured in the Firebase Console (3 emails wired via `.env`).
- `RUTRACKER_USERNAME` / `RUTRACKER_PASSWORD` — REAL.
- Both `keystores/{debug,release}.keystore` present.

This release is consequently distribute-eligible. The 1.2.17-1037 "NOT distributed" note is no longer load-bearing.

Lava-Android-1.2.17-1037 / Lava-API-Go-2.3.6-2306 — 2026-05-13 (§6.X-debt PARTIAL CLOSE + §6.L 21st-23rd invocations)

Previous published: Lava-Android-1.2.16-1036 / Lava-API-Go-2.3.5-2305

Constitutional

- **§6.X added (TWENTY-FIRST §6.L invocation).** Container-Submodule Emulator Wiring Mandate — every Android emulator the project depends on for testing MUST execute its emulator process INSIDE a podman/docker container managed by `submodules/containers/`. Propagated to 52 docs (root × 2 + 16 submodules × 3 + lava-api-go × 3). Mechanical enforcement via `scripts/check-constitution.sh` (inheritance presence checks).
- **§6.X-debt PARTIAL CLOSE (TWENTY-SECOND §6.L invocation).** Containers submodule commit `562069e7` ships:
  - `pkg/emulator/containerized.go` — Containerized type implementing the Emulator interface via podman/docker `run -d --device /dev/kvm`.
  - `pkg/emulator/containerized_test.go` — 9 test functions / 12 sub-cases with Bluff-Audit rehearsal (mutating `"--device"`, `"/dev/kvm"` out of Boot args produces "captured args missing --device /dev/kvm").
  - `pkg/emulator/Containerfile` + `entrypoint.sh` — Android emulator image recipe (Linux x86_64 buildable; darwin/arm64 blocked per §6.V-debt).
  - `cmd/emulator-matrix/main.go` — `--runner=host-direct|containerized` flag + `--container-image` + `--container-runtime`.
- **§6.X runtime checks (a) + (b) activated** in Lava parent `scripts/check-constitution.sh`. Both falsifiability-rehearsed (`mv` / `sed` mutations produce "MISSING 6.X runtime check (...)").
- **§6.L invocation count: TWENTY → TWENTY-THREE.** Operator invoked the Anti-Bluff Functional Reality Mandate three times in this session window. Verbatim restatement of the no-bluff covenant propagated across all 52 constitutional docs.

Build infrastructure (not user-visible)

- Submodule pin: `submodules/containers` 8197c222 → 562069e7+ (full §6.X-debt close set).
- `scripts/check-constitution.sh` gains 5 new lines + 2 new runtime checks; the existing inheritance checks are reorganized.

What's NOT in this version

- **No Firebase distribute.** Per operator's 23rd §6.L invocation: rebuild
  - redistribute requires real `app/google-services.json` + real `LAVA_FIREBASE_TOKEN`. Both are placeholders in this commit. Distributing with stub secrets produces signed-but-broken APKs (Firebase init crashes on `LavaApplication.onCreate`) — that's the canonical §6.J "tests green, feature broken for users" bluff this mandate exists to prevent.
- **No §6.X gate run.** The Containers/cmd/emulator-matrix `--runner= containerized` path requires Linux x86_64 with `/dev/kvm`; this build is on darwin/arm64. Real-stack boot test recorded as honestly outstanding per §6.V-debt incident JSON.

Operator inputs needed for the next distribute

1. Real `app/google-services.json` (not the stub).
2. Real `LAVA_FIREBASE_TOKEN` in `.env`.
3. Real `RUTRACKER_USERNAME` + `RUTRACKER_PASSWORD` (for C02 verification).
4. Real `KINOZAL_USERNAME`/`KINOZAL_PASSWORD` (for C09).
5. Real `NNMCLUB_USERNAME`/`NNMCLUB_PASSWORD` (for C10).
6. Linux x86_64 gate host (or remote runner) for the §6.X attestation producing `runner: containerized` rows.

Changelog

Lava-Android-1.2.16-1036 / Lava-API-Go-2.3.5-2305 — 2026-05-12 (debug icon + RuTracker-Main full removal + §6.L 19th)

Previous published: Lava-Android-1.2.15-1035 / Lava-API-Go-2.3.4-2304

Fixed

- **Debug launcher icon background.** The debug variant's `ic_launcher_background` is now solid `#00FF00` (green) instead of the previous gray. Added a debug-specific adaptive-icon at `app/src/debug/res/mipmap-anydpi-v26/ic_launcher.xml` pointing at the debug drawable so both `android:icon` and `android:roundIcon` references in the manifest pick up the green background in the `.dev` variant only.
- **Debug app name.** `app/src/debug/res/values/strings.xml`'s `app_name` changed from "Lava Dev" → "Lava DEV" per operator.
- **RuTracker (Main) persisting through reinstall.** v1.2.15 hid the seed entry but existing installs and Android Auto Backup restores carried the row back. Three layers of defense:
  1. `EndpointsRepositoryImpl.observeAll()` now `purgeRutrackerLegacy()`s the DAO on every observe() start AND filters `Endpoint.Rutracker` out of the emitted list.
  2. `EndpointsRepositoryImpl.add()` silently rejects `Endpoint.Rutracker` arguments.
  3. `PreferencesStorageImpl.getSettings()` migrates a persisted `Endpoint.Rutracker` (e.g., from a backup restore) to `Endpoint.GoApi(host = "lava-api.local")` and clears the prefs key.
- **Auto Backup / cloud-restore exclusion.** Added `app/src/main/res/xml/backup_rules.xml` + `app/src/main/res/xml/data_extraction_rules.xml` excluding `settings.xml` SharedPreferences from full-backup, cloud-backup, and device-transfer paths. Manifest now declares both via `android:fullBackupContent` and `android:dataExtractionRules`. Once a user removes a server, a reinstall (and any future backup restore) will NOT re-introduce stale endpoints.

New tests

- `EndpointsRepositoryImplFilterTest` (JVM): asserts the filter + purge + add-rejection contracts.
- `Challenge26RutrackerMainAbsentFromServerListTest` (Compose UI): asserts the Server section never renders "Main" or "rutracker.org" entries.

Constitutional

- §6.L mandate invoked for the 19th time. Count propagated across CLAUDE.md, AGENTS.md, lava-api-go's CLAUDE/CONSTITUTION/AGENTS, and all 48 docs across the 16 vasic-digital submodules.

Changed

- Go API version → 2.3.5-2305

- Android version → 1.2.16-1036

Lava-Android-1.2.15-1035 / Lava-API-Go-2.3.4-2304 — 2026-05-12 (operator-reported UX issues)

Previous published: Lava-Android-1.2.14-1034 / Lava-API-Go-2.3.3-2303

Fixed

- **Onboarding wizard not shown on clean install.** MainActivity's `showOnboarding` defaulted to `false` and was loaded asynchronously, while `setKeepOnScreenCondition` only waited for theme — not for onboarding-status. Fresh-install users could see MainScreen before the onboarding flag was loaded → wizard never appeared. Fixed by making `showOnboarding` nullable and extending the splash-keep condition to wait for both theme AND onboarding-status to load.
- **Menu provider color-dot spacing.** Provider rows in the Menu screen had a `small` spacer between the color dot and the provider name — too tight visually. Bumped to `medium`.
- **Theme change required app restart.** `MainActivity` collected only the `first()` emission of `viewModel.theme` and never observed subsequent changes. Theme picker writes to preferences (reactive Flow) but the Activity didn't recompose. Fixed by switching to `viewModel.theme.collect { ... }` so each emission updates the composition immediately.
- **Server section: RuTracker (Main) removed from seeded list.** Per the operator's directive "communication is now strictly through the Lava API", the historical direct rutracker.org seed entry (`Endpoint.Rutracker`) is no longer surfaced to the user. The `defaultEndpoints` seed in `EndpointsRepositoryImpl` is now empty; discovery + manual-add populate the list. The `Endpoint.Rutracker` type remains as a fallback constant for now; full type deletion is documented as a follow-up SP because of its ~15 cascading call-site touches.
- **Server section: trash icon + confirmation dialog for offline endpoints.** Each `Mirror` / `GoApi` row in the Connections list that is `removable && !selected && status != Active` now shows a red trash (Delete) icon directly (no need to toggle edit mode). Tapping it shows a confirmation `Dialog` ("Remove server? — Remove %s from the server list? This cannot be undone."). Confirm → removal; Cancel → no-op. The edit-mode Remove icon was also updated to use the trash icon and now routes through the same confirmation dialog.

Live-emulator verification

- 9-Challenge sweep on CZ_API34_Phone API 34 (post-fix re-run): PASS.
- New Compose UI Challenge: `Challenge25OnboardingFreshInstallTest` verifies the splash + onboarding-wizard rendering on clean prefs.

Changed

- Go API version → 2.3.4-2304
- Android version → 1.2.15-1035

Lava-Android-1.2.14-1034 / Lava-API-Go-2.3.3-2303 — 2026-05-12 (§6.L 16th+17th invocation: C03 fix + Cloudflare anti-bot + anti-bluff audit)

Previous published: Lava-Android-1.2.13-1033 / Lava-API-Go-2.3.2-2302

Fixed

- **C03 RuTor anonymous onboarding** — Onboarding flow stuck on Configure screen for users picking RuTor with the Anonymous Access toggle on. Root cause: `OnboardingViewModel.onTestAndContinue()` called `sdk.checkAuth()` on the anonymous branch and treated `AuthState.Unauthenticated` as failure — but Unauthenticated IS the user's chosen state for anonymous. Fixed by skipping `checkAuth` on the anonymous branch entirely. (Commit `4d27c07`)

- **Credential-leak-in-logs (§6.H)** — `OnboardingViewModel.perform()` logged actions via `logger.d { "Perform $action" }` which printed the operator's real RuTracker username + password in plain text via the sealed-class auto-`toString` of `UsernameChanged(value=…)` / `PasswordChanged(value=…)`. Discovered during the C03 investigation. Fixed by printing only `action::class.simpleName`. (Commit `4d27c07`)

- **C02 RuTracker login — Cloudflare anti-bot stall** — POST to `/forum/login.php` was silently stalled by Cloudflare's anti-bot (TLS+TCP succeeded, request body written, no response data ever returned). Mitigation: HttpCookies plugin + browser-class headers (Accept, Accept-Language, Accept-Encoding) + real

Chrome 124 UA + pre-flight `GET /forum/index.php` so the POST carries Cloudflare clearance cookies. POST now returns 302→200. (Commit `f7d0a62`)

- **rutracker cookie selection bug** — `RuTrackerInnerApiImpl.login()` picked the wrong cookie as the rutracker session token when Cloudflare added `cf_clearance` to Set-Cookie headers. Tightened selection to match by NAME prefix (bb_data/bb_session/bb_login) instead of fragile "not bb_ssl" negation. (Commit `f7d0a62`)

- **HTTP timeouts** — Main + LAN OkHttp clients had no explicit timeouts (OkHttp default 10s — too tight for slow networks). Set explicit 30s connect/read/write. Rutracker Ktor client gets HttpTimeout plugin (60s request, 30s connect, 60s socket). (Commit `4d27c07`)

- **Challenge16 stale-assumption bluff** — Test asserted "Internet Archive must NOT appear in onboarding list" while Phase 2b had flipped `apiSupported=true` on archiveorg. The test passed only because its `waitUntil` accepted the Welcome screen (where no provider list renders). Rewritten to navigate to "Pick your providers" and assert that all 4 verified+apiSupported providers actually render. (Commit `4b0dd55`)

- **GetCurrentProfileUseCase brittle parser** — Single-selector Jsoup approach (`#logged-in-username`) failed after Cloudflare mitigation changed the served page. Added 4-selector fallback chain. (Commit `4b0dd55`)

- **FirebaseAnalyticsTracker verify-only test** — Two tests used `verify { mock.foo() }` as their sole assertion (§6.L clause 4 Forbidden Test Pattern). Refactored to `mockk slot` captures with `assertEquals` on captured values. (Commit `4b0dd55`)

Constitutional

- §6.L mandate invoked for the 16th + 17th times. Count propagated across CLAUDE.md, AGENTS.md, lava-api-go's CLAUDE/CONSTITUTION/AGENTS, and all 48 docs across the 16 vasic-digital submodules. (Commits `4b0dd55`, `d8b90ab`, this commit)

Live-emulator Challenge Test verification (CZ_API34_Phone API 34)

- **PASS** (14 of 24): C00, C01, C03, C04, C05, C06, C07, C08, C09, C10, C11, C12, C13, C14, C15, C16 (rewritten), C20, C21, C22 (in isolation), C23, C24.

- **PARTIAL** (1): C02 — Cloudflare mitigation portion verified; blocked at `parseUserId` post-login (none of 4 selectors match today's rutracker HTML — needs scraper archaeology or operator credential verification).
- **HONEST SHALLOW SCOPE** (C04-C08): test classes named after deep features (DownloadTorrentFile, ViewTopicDetail, CrossTrackerFallback) but only assert "tab is visible" per their KDocs (gap forensic in `.lava-ci-evidence/sp3a-challenges/C4-2026-05-04-redesign.json`). Deep tests owed.

Unit-test suite

- 421 unit tests across all modules, 0 failures, 0 errors.

Verified bluff-pattern audit (across all `*Test.kt` files)

- 0 mock-the-SUT bluffs.
- 0 `@Ignore` without issue link.
- 1 verify-only test (FirebaseAnalyticsTrackerTest) — fixed.
- 1 stale-assumption test (Challenge16ApiSupportedFilterTest) — rewritten.

Changed

- Go API version → 2.3.3
- Android version → 1.2.14

Lava-Android-1.2.13-1033 / Lava-API-Go-2.3.2-2302 — 2026-05-08 (Yole+Boba 8-palette theme system)

Yole semantic color foundation with 8 distinct palettes from Boba project accents.

Lava-Android-1.2.12-1032 / Lava-API-Go-2.3.2-2302 — 2026-05-08 (Release build)

Previous published: Lava-Android-1.2.11-1031 / Lava-API-Go-2.3.2-2302

First production release build with full signing + ProGuard optimization. Includes all fixes from 1.2.9+1.2.10.

Lava-Android-1.2.11-1031 / Lava-API-Go-2.3.2-2302 — 2026-05-08

Previous published: Lava-Android-1.2.10-1030 / Lava-API-Go-2.3.1-2301

(incremental release — see git log for details)

Lava-Android-1.2.10-1030 / Lava-API-Go-2.3.1-2301 — 2026-05-08 (Docker auth fix)

Previous published: Lava-Android-1.2.9-1029 / Lava-API-Go-2.3.0-2300

Fixed

- docker-compose.yml: pass LAVA_AUTH_FIELD_NAME, LAVA_AUTH_HMAC_SECRET, LAVA_AUTH_ACTIVE_CLIENTS, LAVA_AUTH_RETIRED_CLIENTS, LAVA_AUTH_TRUSTED_PROXIES to lava-api-go container (was crashing on startup)

Changed

- Go API version → 2.3.1

Lava-Android-1.2.9-1029 / Lava-API-Go-2.3.0-2300 — 2026-05-08 (Theme fix + anti-bluff onboarding)

Previous published: Lava-Android-1.2.8-1028 / Lava-API-Go-2.2.0-2200

Fixed — Theme readability (critical)

- LavaTheme now wires MaterialTheme.colorScheme from AppColors, fixing dark-mode text being unreadable (MaterialTheme.colorScheme returned light-theme defaults even in dark mode)
- AppColors extended with secondary, tertiary, surfaceVariant, onSurfaceVariant, error roles

- All custom themes (Ocean/Forest/Sunset) updated with full Material3 color roles

Fixed — Onboarding wizard

- WelcomeStep shows provider count ("6 providers available") per design spec
- ConfigureStep back press now goes to Providers per spec (was going to previous provider)
- SummaryStep hardcoded colors replaced with AppTheme accents (§6.R No-Hardcoding fix)
- All onboarding steps use AppTheme.colors/typography/shapes instead of MaterialTheme defaults
- Anonymous provider TestAndContinue no longer erroneously calls checkAuth for health validation

Added — Anti-bluff tests

- 16 OnboardingViewModel unit tests (all passing): step transitions, provider toggling, back press, anon/auth TestAndContinue, credential saving, Finish signaling, filtering
- 3 Challenge Tests (C20-C22) for onboarding wizard — compile, need emulator to execute

Changed — Constitution

- §6.J/§6.L/§6.Q added to core/, feature/, app/ CLAUDE.md + AGENTS.md (6 files)
- Lava constitution inheritance added to Panoptic submodule (CLAUDE/AGENTS/CONSTITUTION)
- FakeTrackerClient now exposes `authState` property for testability
- Duplicate include(":feature:onboarding") removed from settings.gradle.kts

Changed — Go API

- version.Name → 2.3.0, Code → 2300

Lava-Android-1.2.8-1028 / Lava-API-Go-2.2.0-2200 — 2026-05-07 (Phases 2-6)

Previous published: Lava-Android-1.2.7-1027 / Lava-API-Go-2.1.0-2100

Added — Multi-provider streaming search (Phase 2)

- `GET /v1/search?q=...&providers=...` SSE endpoint fans out to all registered providers
- `SseClient` (OkHttp-based SSE parser), `ProviderChipBar` multi-select filter
- Provider label chips on search result cards
- `apiSupported=true` on all 6 providers (rutracker, rutor, nnmclub, kinozal, archiveorg, gutenberg)
- Provider result filtering chips on search results screen

Added — Onboarding wizard (Phase 3)

- New `:feature:onboarding` module with 4-step wizard: Welcome → Pick Providers → Configure → Summary
- AnimatedContent sliding transitions
- Connection auto-test on credential submit, closes app on back press at Welcome

Added — Sync expansion (Phase 4)

- Device identity UUID generated on first launch
- Sync Now buttons on Favorites and Bookmarks screens
- History and Credentials sync categories with WorkManager workers
- Menu sync settings expanded from 2 to 4 categories

Changed — UI/UX polish (Phase 5)

- Menu multi-provider header showing all signed-in providers with sign-out
- Ocean/Forest/Sunset color themes alongside SYSTEM/LIGHT/DARK
- About dialog shows versionCode: "Version: 1.2.8 (1028)"
- Credentials screen modern redesign with ProviderColors, nav-bar FAB fix
- Nav-bar overlap audit: `navigationBarsPadding` added at Scaffold level

Added — Crashlytics (Phase 6)

- Non-fatal `recordException` tracking in 8 ViewModels across all error paths

Fixed

- Hardcoded `thinker.local:8443` → config-driven via `ObserveSettingsUseCase`
- Credentials FAB no longer overlaps 3-button navigation bar

All notable changes to **Lava** (the Android client and the lava-api-go service) are documented in this file.

Per constitutional clause **§6.P (Distribution Versioning + Changelog Mandate)**, every distributed build MUST appear here BEFORE `scripts/firebase-distribute.sh` is run. The script refuses to operate without a matching entry.

The format follows Keep a Changelog loosely, adapted to a multi-artifact repository. Each release tag lives on the four-mirror set (GitHub, GitLab, GitFlic, GitVerse).

Tag formats:

- `Lava-Android-<version>-<code>` — Android client.
- `Lava-API-Go-<version>-<code>` — Go API service (`lava-api-go`).
- `Lava-API-<version>-<code>` — legacy Ktor proxy (`:proxy`).

The `<code>` suffix is the integer version code (Android `versionCode`, api-go `version.Code`).

Per-version distribution snapshots (the exact text shipped as App Distribution release-notes) live under `.lava-ci-evidence/distribute-changelog/<channel>/<version>-<code>.md`.

Lava-API-Go-2.1.0-2100 — 2026-05-06 (Phase 1)

Channel: container registry / remote distribution to thinker.local
Previous published: Lava-API-Go-2.0.16-2016 (2026-05-06)

Added — API auth + transport (Phase 1 of `docs/todos/Lava_TODOs_001.md`)

- **UUID-based client allowlist** enforced via the `Lava-Auth` header (name itself config-driven via `LAVA_AUTH_FIELD_NAME` per §6.R). Active vs retired separation: retired UUIDs return `426 Upgrade Required` with min-version JSON instead of advancing the backoff counter.
- **Per-IP fixed-ladder backoff** (`2s,5s,10s,30s,1m,1h` configurable via `LAVA_AUTH_BACKOFF_STEPS`) shipped as the `pkg/ladder` primitive upstream-contributed to `submodules/ratelimiter`.

- **HTTP/3 preferred** with HTTP/2 fallback + `Alt-Svc` advertisement.
- **Brotli response compression** when the client sends `Accept-Encoding: br`.
- **Prometheus protocol metric** — `lava_api_request_protocol_total{protocol,status}`.
- **Constitutional clause §6.R** — No-Hardcoding Mandate (added to root + 16 submodules + AGENTS.md).

Tests (§6.G real-stack + §6.A contract + §6.N rehearsals)

- 8 integration tests under `lava-api-go/tests/integration/` (active, retired, unknown, ladder, reset, brotli, alt-svc, metric).
- 1 contract test asserting `LAVA_AUTH_FIELD_NAME` does NOT appear as a literal in production source.
- All Bluff-Audit stamps recorded with crisp failure messages from deliberate-mutation rehearsals.

Submodule pin

- `submodules/ratelimiter` pinned at `3faf7a51` (introduces `pkg/ladder/`).

Versions in this build

- lava-api-go: 2.1.0 (2100)
- Android: 1.2.7 (1027) — paired with this API release

Lava-Android-1.2.7-1027 — 2026-05-06 (Phase 1)

Channel: Firebase App Distribution **Previous published:** Lava-Android-1.2.6-1026 (2026-05-05)

Added — client-side auth foundation

- **`AuthInterceptor`** — OkHttp interceptor decrypts the per-build encrypted UUID, injects it into the `Lava-Auth` header, zeroizes the plaintext bytes in `finally`. Auth UUID memory hygiene per `core/CLAUDE.md` (added in this release).
- **Build-time encryption (Phase 11)** — Gradle task `generateLavaAuthClass{Debug,Release}` reads `.env` + the variant keystore and emits `lava.auth.LavaAuthGenerated` containing the AES-GCM-encrypted UUID + nonce + pepper bytes. Generated dir is gitignored.

- **L2 client-side obfuscation** — AES-256-GCM keyed by `HKDF-SHA256(salt = SHA256(signing-cert)[:16], ikm = pepper)`. A re-signed APK has a different cert hash → different derived key → decrypt fails closed.
- **α-hotfix: TrackerDescriptor.apiSupported** filter — the user-facing provider list now hides Internet Archive (and other providers without lava-api-go routes) until Phase 2 ships per-provider routing. Closes the alice-bug class.
- **C15 + C16 Compose UI Challenge Tests** — boot-with-AuthInterceptor + apiSupported-filter rendering assertions.

Tests

- HKDFTest (RFC 5869 §A.1 vector), AesGcmTest (round-trip + tamper detection), SigningCertProviderTest (digest math), AuthInterceptorTest (header injection + empty-blob skip + re-signed-APK fail-closed).

Versions in this build

- Android: 1.2.7 (1027)
- lava-api-go: 2.1.0 (2100) — required for full auth flow

Lava-API-Go-2.0.16-2016 — 2026-05-06

Channel: container registry / remote distribution to thinker.local
Previous published: Lava-API-Go-2.0.15-2015 (2026-05-06)

Fix (post-Ktor cleanup, §6.J bluff in `lava-containers` CLI)

The `lava-containers` workstation CLI had three commands (`build`, `status`, `logs`) that silently targeted dead surfaces post-Ktor-:proxy-removal:

- **`-cmd=build`** — `Manager.BuildImage()` shelled `<runtime> build -t digital.vasic.lava.api:latest ./proxy`. The `./proxy` directory was deleted in 2.0.12 (commit `a00b28f`), so this command would fail at runtime.
- **`-cmd=status`** — `Manager.isHealthy()` probed `http://localhost:8080/`. The api-go service listens on `https://localhost:8443/health`. Status would always report `Healthy: false` even when api-go was running locally.
- **`-cmd=logs`** — `Manager.Logs()` called `<runtime> logs lava-proxy`. The `lava-proxy` service was removed from `docker-compose.yml` in 2.0.12; the active service is `lava-api-go`.

- **`internal/runtime.Runtime.IsHealthy()` + `ContainerIP()`** — both filtered on `name=lava-proxy`. Now `LavaContainerName = "lava-api-go"`.

That's a textbook §6.J bluff: the tool reports outcomes from probing nothing.

Changes

- `internal/orchestrator/manager.go` — full rewrite of broken paths:
  - `ServiceName = "lava-api-go"` (was `"lava-proxy"`)
  - `DefaultPort = "8443"` (was `"8080"`)
  - `BuildImage()` now invokes `<runtime> compose --profile api-go build` — uses the `build:` directive in `docker-compose.yml`'s `lava-api-go` service entry (context: `.`, dockerfile: `lava-api-go/docker/Dockerfile`, target: `runtime`).
  - `isHealthy()` probes `https://localhost:8443/health` with `InsecureSkipVerify: true` (LAN cert is self-signed; this is a local-dev liveness probe, not a security gate).
  - `Status()` prints "Lava API Container Status" instead of "Lava Proxy"; URL line shows the HTTPS health endpoint.
  - Dead methods deleted: `Start()`, `Stop()`, `printStatus()` — never called from `main.go` post-2.0.13 (the Orchestrator type owns compose-up/down).
  - Package doc comment rewritten — was still describing the removed Ktor proxy.
- `internal/runtime/runtime.go` — `IsHealthy()` and `ContainerIP()` now reference `LavaContainerName = "lava-api-go"` constant (was hardcoded `"lava-proxy"`).
- `internal/orchestrator/orchestrator.go` — doc comment updated; `Profile` field doc narrowed to `"api-go"` (was `"api-go" | "legacy" | "both"`).
- `internal/orchestrator/orchestrator_test.go` — three tests retargeted from legacy/both profile names to realistic `api-go + observability + dev-docs` compositions (the Orchestrator type passes profile names through opaquely, but tests should reflect the validated set).

New §6.A real-binary contract test

- `internal/orchestrator/manager_test.go` — `TestManagerConstantsMatchCompose` asserts `ServiceName + DefaultPort` match `docker-compose.yml`'s `container_name:` and `LAVA_API_LISTEN:` entries. `TestManagerConstantsAreNonLegacy` is a regression guard against the legacy `"lava-proxy"`/`"8080"` values.
- Falsifiability rehearsal recorded in commit body (Bluff-Audit stamp). Both mutations produce crisp failure messages with explicit forensic context.

Verification

- `go vet ./...` in `tools/lava-containers`: green.
- `go test ./...` in `tools/lava-containers`: 9 tests across 2 packages PASS (was 7).
- All 31 hermetic bash test suites: green.
- thinker.local API (the running 2.0.13 binary, unchanged): `{"status":"alive"}`, `{"status":"ready"}`.

Versions in this build

- lava-api-go: 2.0.16 (2016) — workstation-CLI cleanup; the api-go binary on thinker.local is unchanged from 2.0.13.
- Android: 1.2.6 (1026) — unchanged.

Lava-API-Go-2.0.15-2015 — 2026-05-06

Channel: container registry / remote distribution to thinker.local
Previous published: Lava-API-Go-2.0.14-2014 (2026-05-06)

Refactor (post-Ktor naming cleanup)

- **`tools/lava-containers/internal/proxy` → `internal/orchestrator`** — renamed the Go package (the "proxy" name was orchestrator-meaning, confusing post-Ktor-removal). `proxy.go` → `manager.go` (the file holds the `Manager` type for compose lifecycle). Imports + call sites updated in `cmd/lava-containers/main.go`. `git mv` preserves file history.
- **`Manager.BuildJar()` removed** — it ran `./gradlew :proxy:buildFatJar` which would fail at runtime since the `:proxy` module is gone. `os/exec` import removed (was only used by `BuildJar`). `Manager.BuildImage()` retained for the api-go image build.
- All `go test ./...` in `tools/lava-containers` PASS post-rename (3 packages).

Versions bumped

Component	Old	New
lava-api-go	2.0.14 (2014)	**2.0.15 (2015)**

Lava-API-Go-2.0.14-2014 — 2026-05-06

Channel: container registry / remote distribution to thinker.local
Previous published: Lava-API-Go-2.0.13-2013 (2026-05-06)

Removed (post-Ktor cleanup, second pass)

- **`tools/lava-containers/cmd/lava-containers/main.go`** — dropped the `legacy` and `both` profile branches. `validateProfile` now accepts only `api-go`. `runStart` no longer carries the `BuildJar` + `BuildImage` fall-through for the deleted Ktor proxy. `mgr.BuildJar()` removed from the `build` command. `autoDetectProjectDir` no longer probes for the deleted `proxy/` directory.
- **`main_test.go`** — `TestValidateProfile_Accepts` reduced to `api-go` only; `legacy` + `both` moved to the rejection table.
- KDoc + comment refresh: header references to "legacy Ktor proxy and/or the new Go API service" reduced to "the lava-api-go service".

Versions bumped

Component	Old	New
lava-api-go	2.0.13 (2013)	**2.0.14 (2014)**

(api-go version bumped per §6.P even though the changes are workstation-side; the bump keeps the distribute pipeline's gate cleanly happy and the per-version snapshot maintains the chain.)

Lava-API-Go-2.0.13-2013 — 2026-05-06

Channel: container registry / remote distribution to thinker.local
Previous published: Lava-API-Go-2.0.12-2012 (2026-05-06)

Fixed (mDNS not reaching the LAN)

- **deployment/thinker/thinker-up.sh: lava-api-go now uses `--network host`** instead of a podman bridge network. The previous bridge-network setup confined JmDNS / mDNS broadcasts to the bridge subnet, so Android testers running Lava could NOT auto-discover thinker.local's API via `_lava-api._tcp`. Matches the local docker-compose.yml pattern where lava-api-go uses `network_mode: host` for the same reason.
- Postgres still uses a bridge network with `127.0.0.1:${POSTGRES_PORT}` published on the host; api-go connects via `127.0.0.1:5432` (host-namespace local).

- Verified: `podman logs lava-api-go-thinker` now shows `mDNS announced port=8443 type=_lava-api._tcp`. Cross-host curl succeeds: `curl https://thinker.local:8443/health` returns `{"status":"alive"}` from the workstation.

Component	Old	New
lava-api-go	2.0.12 (2012)	**2.0.13 (2013)**

Lava-API-Go-2.0.12-2012 — 2026-05-06

Channel: container registry / remote distribution to thinker.local
Previous published: Lava-API-Go-2.0.11-2011 (2026-05-06)

Removed

- **Legacy Ktor proxy** removed from the codebase. Going forward, lava-api-go (Go) is the only API. Files removed: `proxy/` (entire module), `:proxy` Gradle include, `proxy/build.gradle.kts` parsing in `build_and_release.sh` + `scripts/tag.sh`, `lava-proxy` service in `docker-compose.yml`, `--legacy` / `--both` profiles from `start.sh` + `stop.sh`. The Android client was already using the lava-api-go endpoint by default.

Versions bumped

Component	Old	New
lava-api-go	2.0.11 (2011)	**2.0.12 (2012)**

Lava-API-Go-2.0.11-2011 — 2026-05-06

Channel: container registry / remote distribution to thinker.local
Previous published: Lava-API-Go-2.0.10-2010 (2026-05-05)

Added

- **scripts/distribute-api-remote.sh** — ships the lava-api-go OCI image tarball + boot script + TLS material to a remote host via passwordless SSH and brings the stack up under rootless Podman. Default target: `thinker.local`. Verifies `/health` end-to-end from the local host before reporting success. `--tear-down` mode tears containers + image down on the remote.

- **deployment/thinker/{thinker.local.env, thinker-up.sh}** — operator-customizable boot config + script that runs on the remote host. Idempotent. Pinned to rootless Podman.
- **docs/REMOTE-DISTRIBUTION.md** — runbook covering initial SSH setup, distribute, verify, tear-down.
- **`.env.example`** documents `LAVA_API_GO_REMOTE_HOST` (default `thinker.local`) + `LAVA_REMOTE_HOST_USER` (default `milosvasic`).

Operational

- Lava-api-go now runs on the LAN host `thinker.local`. The local workstation tears down its containers + image at end-of-distribute and only builds going forward. Android clients reach the API via mDNS discovery (no client-side change needed).

Versions bumped this cycle

Component	Old	New
lava-api-go	2.0.10 (2010)	**2.0.11 (2011)**
Android `:app`	1.2.6 (1026)	(unchanged)
Ktor proxy	1.0.5 (1005)	(unchanged)

Constitutional bindings

- §6.J — distribute script propagates failures
- §6.B — `/health` end-to-end probe, not just `podman ps`
- §6.K — image produced via the container build path
- §6.M — rootless Podman; no host power-management
- §6.P — this entry IS the §6.P-mandated changelog; per-version snapshot at `.lava-ci-evidence/distribute-changelog/container-registry/2.0.11-2011.md`

Lava-Android-1.2.6-1026 — 2026-05-05

Channels: Firebase App Distribution (debug + release) **Previous published:** Lava-Android-1.2.5-1025 (2026-05-05 23:43 UTC)

Fixed (Crashlytics-driven, §6.O closure-log mandate)

- **fix(tracker-settings): Trackers-from-Settings crash (nested LazyColumn inside Column(verticalScroll))** — operator-reported via Crashlytics. Closure log at `.lava-ci-evidence/crashlytics-resolved/2026-05-05-tracker-settings-nested-scroll.md`. Replaced `LazyColumn` with plain `Column` in

`TrackerSelectorList` since the tracker list is bounded (≤ 6 entries). Validation: 2 structural tests in `feature/tracker_settings/src/test/.../TrackerSelectorListLazyColumnRegressionTest.kt`. Challenge: `app/src/androidTest/.../Challenge14TrackerSettingsOpenTest.kt`. Falsifiability rehearsal recorded.

Added

- **§6.Q Compose Layout Antipattern Guard** — root constitution forbids nesting vertically-scrolling lazy layouts (LazyColumn, etc.) inside parents giving unbounded vertical space (verticalScroll, etc.). Per-feature structural tests + Challenge Tests on the §6.I matrix are the gates. Propagated to AGENTS.md.

Versions bumped this cycle

Component	Old	New
Android `:app`	1.2.5 (1025)	**1.2.6 (1026)**
Ktor proxy	1.0.5 (1005)	(unchanged)
lava-api-go	2.0.10 (2010)	(unchanged)

The 1.2.6 cycle is Android-only — proxy + lava-api-go did not require new fixes.

Lava-Android-1.2.5-1025 — 2026-05-05

Channels: Firebase App Distribution (debug + release) **Previous published:** Lava-Android-1.2.4-1024 (2026-05-05 23:25 UTC)

Fixed (preemptive Hilt-graph hardening)

- **fix(firebase): Hilt @Provides for Firebase SDKs now tolerates getInstance() throwing.** Pre-1.2.5, a feature ViewModel that injects `AnalyticsTracker` (Login, ProviderLogin, Search, Topic) would crash on construction if `FirebaseAnalytics.getInstance(context)` / `FirebaseCrashlytics.getInstance()` / `FirebasePerformance.getInstance()` threw. The 1.2.3 → 1.2.4 fix only hardened the LavaApplication path, not the Hilt graph. 1.2.5 closes that gap:
  - `FirebaseProvidesModule` wraps each SDK accessor in `runCatching { ... }.getOrNull()` and provides nullable types.
  - `FirebaseAnalyticsTracker` accepts nullable SDKs and `runCatching`-guards every per-call SDK invocation.

    - New `NoOpAnalyticsTracker` is selected by the AnalyticsTracker `@Provides` when both Crashlytics and Analytics are unavailable.
    - Validation: `app/src/test/.../FirebaseAnalyticsTrackerTest.kt` (4 tests covering null SDKs, throwing SDK, present SDK forwarding).

Added

- §6.P enforcement extended to `scripts/tag.sh` — refuses tags lacking CHANGELOG.md entry or per-version distribute-changelog snapshot, for android + api + api-go.
- Bluff-hunt evidence record at `.lava-ci-evidence/bluff-hunt/2026-05-05-firebase-and-distribute-mandates.json` covering 5 falsifiability rehearsals + 2 production-code targets per §6.N.2.
- Per-version distribute-changelog snapshots for the proxy (1.0.5-1005) and api-go (2.0.10-2010) channels.

Versions bumped this cycle

Component	Old	New
Android `:app`	1.2.4 (1024)	**1.2.5 (1025)**
Ktor proxy	1.0.5 (1005)	(unchanged)
lava-api-go	2.0.10 (2010)	(unchanged)

The 1.2.5 cycle is Android-only — proxy + lava-api-go did not require new fixes; their 1.2.4-cycle versions stay current.

Lava-Android-1.2.4-1024 — 2026-05-05

Channels: Firebase App Distribution (debug + release) **Previous published:** Lava-Android-1.2.3-1023 (2026-05-05 22:33 UTC)

Fixed

- **fix(firebase): harden Firebase init against the 2 Crashlytics crashes recorded against 1.2.3 (1023)** — closure log at `.lava-ci-evidence/crashlytics-resolved/2026-05-05-firebase-init-hardening.md`. Removed redundant `FirebaseApp.initializeApp(this)` (FirebaseInitProvider auto-init covers it; the explicit call raced with StrictMode in some launches). Extracted Firebase init into testable `FirebaseInitializer` with per-SDK `runCatching` guards. Added Firebase keep rules to `app/proguard-rules.pro` since the BOM consumer rules don't fully cover R8 stripping of reflective entry points. Validation test: `app/src/test/.../`

`FirebaseInitializerTest.kt` (5 tests). Challenge Test: `app/src/androidTest/.../Challenge13FirebaseColdStartResilienceTest.kt`. Falsifiability rehearsal recorded in commit body. Commit: `6758b73`.

Added

- **AnalyticsTracker wired into real user paths** — `LoginViewModel`, `SearchViewModel`, `TopicViewModel`, `ProviderLoginViewModel` emit canonical events (`lava_login_submit`, `lava_login_success`, `lava_login_failure`, `lava_search_submit`, `lava_view_topic`, `lava_download_torrent`, `lava_download_torrent_failure`) via the Hilt-injectable `AnalyticsTracker` interface. Implementation lives in `:app` (`FirebaseAnalyticsTracker`) so feature modules remain reusable per the Decoupled Reusable Architecture rule. Commits: `6758b73`, follow-up.
- **lava-api-go FirebaseTelemetry middleware** at `internal/middleware/firebase.go` — Gin middleware that records 5xx + recovered panics as Firebase non-fatals; 4xx + 2xx logged as events. Wired into `cmd/lava-api-go/main.go` `buildRouter`. 6 unit tests with falsifiability rehearsal. Honest no-op fallback when no service-account key configured.

Constitution / Process

- **§6.O Crashlytics-Resolved Issue Coverage Mandate** — every Crashlytics-resolved issue requires (a) validation test, (b) Challenge Test, (c) closure log under `.lava-ci-evidence/crashlytics-resolved/`. Propagated to all 16 vasic-digital submodules + lava-api-go's three doc files. Constitution checker hard-fails on missing §6.O reference in any of the 21+ doc trios. Commits: `6758b73`, `017da23`.
- **§6.P Distribution Versioning + Changelog Mandate** — every distribute action requires strictly increasing versionCode + matching CHANGELOG.md entry + per-version snapshot. `scripts/firebase-distribute.sh` enforces both gates. **This entry is the inaugural application of §6.P.**

Lava-Android-1.2.3-1023 — 2026-05-05 22:33 UTC

Channel: Firebase App Distribution (inaugural) **Previous published:** N/A (first Firebase-instrumented build)

Added (inaugural Firebase integration)

- Crashlytics + Analytics + Performance Monitoring wired in `LavaApplication.kt`.
- App Distribution replaces local `releases/` flow as canonical operator delivery channel.
- 5 distribution scripts under `scripts/`: `firebase-env.sh`, `firebase-setup.sh`, `firebase-distribute.sh`, `firebase-stats.sh`, `distribute.sh`.
- Tester roster loaded from `.env` (`LAVA_FIREBASE_TESTERS_*`).
- 2 anti-bluff bash regression tests under `tests/firebase/` (no WARN-swallow + gitignore-coverage).
- `lava-api-go/internal/firebase/` server-side skeleton with no-op fallback when service-account key absent.

Commit: `e9de508`.

lava-api-go	2.0.8 (2008)	2.0.9 (2009)

Lava-Android-1.2.0-1020 — 2026-05-01

First release of the **multi-tracker SDK foundation** (SP-3a). The Android client now supports two trackers — RuTracker (existing) and RuTor (new) — with user-selectable active tracker, custom mirrors, mirror health tracking, and an explicit cross-tracker fallback flow.

Added

- **RuTor (rutor.info / rutor.is) tracker support** — anonymous-by- default per decision 7b-ii; capabilities `SEARCH + TOPIC + DOWNLOAD`.
- **Tracker selection UI in Settings → Trackers** — list of registered trackers, single-tap to switch the active tracker, per-tracker health summary.
- **Custom mirror entry per tracker** — operators can add mirrors beyond the bundled defaults; persisted in Room (`tracker_mirror_user`).
- **Mirror health tracking** — periodic `MirrorHealthCheckWorker` (15-min interval) probes each registered mirror; status `HEALTHY` / `DEGRADED` / `UNHEALTHY` persisted in `tracker_mirror_health`.
- **Cross-tracker fallback modal** — when all mirrors of the active tracker hit `UNHEALTHY`, the SDK emits `CrossTrackerFallbackProposed`; the UI presents a modal offering the alternative tracker. Accept → re-issues the call on the alt tracker; dismiss → explicit failure UI (snackbar). No silent fallback.
- **`docs/sdk-developer-guide.md` (partial draft)** — 7-step recipe for adding a third tracker, paper-traced through the existing RuTor module.
- **8 Compose UI Challenge Tests** under `app/src/androidTest/kotlin/lava/app/challenges/` (C1-C8) — each with a documented falsifiability rehearsal protocol.

Changed

- **Internal: RuTracker implementation now fully decoupled behind the multi-tracker SDK.** `core/network/rutracker` git-moved to `core/tracker/rutracker`. `RuTrackerClient` implements `TrackerClient` + applicable feature interfaces (Searchable, Browsable, Topic, Comments, Favorites, Authenticatable, Downloadable). `SwitchingNetworkApi` now delegates to `LavaTrackerSdk` rather than to a single hard-wired client.
- **New `vasic-digital/Tracker-SDK` submodule mounted at `submodules/tracker_sdk/`.** Generic primitives (registry, mirror-config store, test scaffolding). Pin is **frozen by default** per the Decoupled Reusable Architecture rule. Mirrored to GitHub + GitLab (2-upstream scope per 2026-04-30 spec deviation).

Constitutional

- **Added clauses 6.D (Behavioral Coverage Contract), 6.E (Capability Honesty), 6.F (Anti-Bluff Submodule Inheritance) to root CLAUDE.md** and cascaded to core/CLAUDE.md, feature/CLAUDE.md, lava-api-go/{CLAUDE,AGENTS}.md, submodules/tracker_sdk/{CLAUDE,CONSTITUTION,AGENTS}.md, and root AGENTS.md.
- **Added the Seventh Law (Anti-Bluff Enforcement, all 7 clauses)** with mechanical pre-push hook enforcement at .githooks/pre-push: Bluff-Audit commit-message stamp on every test commit, mock-the- SUT pattern rejection, hosted-CI config rejection. The Seventh Law is binding on every test commit and on every release tag — scripts/tag.sh refuses to operate without .lava-ci-evidence/<TAG>/real-device-verification.md at status VERIFIED and per-Challenge-Test attestation files.
- **Local-Only CI/CD apparatus** materialized as scripts/ci.sh (single entry point, three modes — --changed-only, --full, --smoke), scripts/check-fixture-freshness.sh, scripts/check-constitution.sh, scripts/bluff-hunt.sh (Seventh Law clause 5 recurring hunt driver). Pre-push hook runs scripts/ci.sh --changed-only. Tag script enforces an Android evidence-pack gate at .lava-ci-evidence/Lava-Android-<version>/.

Phases (commit summary)

The SP-3a development arc spans 6 phases (Phase 0 audit + Phases 1–5 implementation). Approximate per-phase commit counts:

Phase	Scope	Commits
0	Pre-implementation audit, ledger seeding, equivalence test scaffolding	5
1	Foundation — core/tracker/api, registry, mirror, testing modules	12
2	RuTracker decoupling — git-mv, RuTrackerClient, parser refit	40
3	RuTor implementation — descriptor, parsers, feature impls, fixtures	41
4	Mirror health, cross-tracker fallback, tracker_settings UI	20
5	Constitution updates, 8 Challenge Tests, scripts/ci.sh, tag gate	26
—	Misc (Seventh Law, JVM-17 hardening, bluff audit, phase wraps)	4
—	Documentation polish (this release)	5
		153

Phase	Scope	Commits
SP-3a total		

Phase 5 closes the implementation arc. Real-device verification (Task 5.22) is the operator-required gate before tagging — see "Known limitations" below.

Known limitations (operator-required gates)

These are NOT bugs; they are explicit acceptance gates the operator MUST satisfy before tagging Lava-Android-1.2.0-1020:

- **Task 5.22 — real-device Challenge Test attestation.** The 8 Compose UI Challenge Tests (`app/src/androidTest/kotlin/lava/app/challenges/`) cannot be run from the agent environment. The operator MUST run each on a real Android device (API 26+, internet-connected), capture the user-visible state per the test's primary assertion, perform the falsifiability mutation listed in the test header, and update each `.lava-ci-evidence/Lava-Android-1.2.0-1020/challenges/C<n>.json` from `PENDING_OPERATOR` to `VERIFIED`. `scripts/tag.sh` refuses to operate without all 8 at `VERIFIED`.
- **Task 5.25 — connectedAndroidTest runner not yet wired into `:app/build.gradle.kts`.** Until the androidx.test runner deps and the `connectedDebugAndroidTest` task are wired, the operator's C1–C8 verification is performed by manually exercising each scenario on the device rather than by the gradle task. This is constitutional debt tracked in `feature/CLAUDE.md`.
- **Task 4.20 — Phase 4 integration smoke on real device.** Phase 4 shipped the cross-tracker fallback modal end-to-end; Task 4.20 is the integration smoke (mirror probe loop + fallback on real rutracker / rutor mirrors). The smoke commit landed (`80975e0 sp3a-4.20`) but the real-device replay falls under the same Task 5.22 gate above.

Latent findings (open + resolved)

Tracked in [`docs/superpowers/specs/2026-04-30-sp3a-coverage-exemptions.md`]:

- **LF-1** — `MenuViewModelTest` holds `TestBookmarksRepository` without exercising it. **OPEN** — tripwire fires when first `MenuAction.ClearBookmarks` test path is added.
- **LF-2** — `TestHealthcheckContract` is currently a future-facing tripwire (lava-api-go has no healthcheck block at HEAD). **OPEN** — tripwire fires the moment a healthcheck is re-introduced.

- **LF-3** — Tracker chain compiles to JVM 21 while Android targets JVM 17. **RESOLVED in Phase 2 Section E wrap-up** (Tracker-SDK pin `b779fda` enforces JVM 17 on every SDK subproject).
- **LF-5** — `RuTrackerDescriptor` declares `UPLOAD` and `USER_PROFILE` without backing feature interfaces. **OPEN** — letter-of-the-law clause 6.E is satisfied (no caller can ask), but the descriptor makes a forward-looking claim with no impl. Triggers before any phase that depends on those capabilities (cross-tracker fallback ranking, SP-3a-bridge).
- **LF-6** — `TorrentItem.sizeBytes` is permanently null for rutracker (the legacy scraper discards the byte count and keeps only the formatted display string in `metadata["rutracker.size_text"]`). **OPEN** — triggers before any cross-tracker comparison logic that needs numeric size.

Fixed

- (none — this release is feature-additive)

Lava-API-1.0.2-1002 — 2026-05-01

Maintenance release of the legacy Ktor proxy. Routine patch bump after a clean re-build + re-test cycle — no behavioral changes vs `Lava-API-1.0.1-1001`.

Operational

- Container image rebuilt against the current submodules/containers pin and pushed to `localhost/lava-proxy:dev` via `./build_and_push_docker_image.sh` / `./build_and_release.sh`.
- Boot verified: `./start.sh --both` brings the proxy up alongside lava-api-go; `lava-containers status` reports `Healthy: true`, LAN IP advertised via mDNS service-type `_lava._tcp.local.` with symmetric TXT records (engine, version, protocols, compression, tls).
- Real-network smoke: `GET http://localhost:8080/` returns `200 OK` after ~1.7s warmup; `GET /forum` returns 142 KB of legacy Ktor scrape output.

Constitutional

- Inherits the new **Seventh Law (Anti-Bluff Enforcement)** added to root `CLAUDE.md` on 2026-04-30. The pre-push hook's Bluff-Audit-stamp gate + forbidden-test-pattern gate apply to all future proxy commits.

Tests

- All 18 `lava-api-go` Go test packages green at HEAD; the proxy's Kotlin-side tests inherit the project-wide Spotless / ktlint / unit-test gate run by `scripts/ci.sh --changed-only`.

Lava-API-Go-2.0.7-2007 — 2026-05-01

Maintenance release of the Go API service. Re-anchors the version to the post-SP-3a HEAD with all consumer-side constitutional infrastructure (submodule mirrors, Seventh Law inheritance, integration-test podman runs) verified against real backends.

Verified — pretag (Sixth Law clause 5 + SP-2 Phase 13.1)

- `lava-api-go/scripts/pretag-verify.sh` exercised the running api-go on `https://localhost:8443` with all 5 scripted black-box probes:
  - `GET /` → `200` (5B, 745ms)
  - `GET /forum` → `200` (142 KB, 920ms)
  - `GET /search?query=test` → `401` (auth gate honored)
  - `GET /torrent/1` → `404` (known empty topic)
  - `GET /favorites` → `401` (auth gate honored)
- Evidence at `.lava-ci-evidence/1f7f3c0610a353048ef1c3d9daffd41f5aa7f7b1.json`.

Verified — integration tests against real podman containers

- **Phase 4.3 cache integration:** 7 tests PASS (1.13s) against `docker.io/postgres:16-alpine` via `scripts/run-test-pg.sh`. Real key generation + Set/Get/Invalidate cycle exercised.
- **Phase 10.2 e2e:** 6 tests PASS (16.49s). Real Gin engine, real auth middleware, real handlers; no mocks below the SUT.
- Evidence at `.lava-ci-evidence/sp2-podman-tests-2026-04-30/integration-evidence.json`.

Constitutional

- Inherits the new **Seventh Law (Anti-Bluff Enforcement)** with seven mechanically-enforced clauses. `lava-api-go/CLAUDE.md` and `lava-api-go/AGENTS.md` reference the Seventh Law's text in the parent Lava `CLAUDE.md`. Bluff-Audit stamps now mandatory on every Go test commit (`*_test.go`).
- All 16 vasic-digital submodules consumed by `lava-api-go` (Auth, Cache, Challenges, Concurrency, Config, Containers,

Database, Discovery, HTTP3, Mdns, Middleware, Observability, RateLimiter, Recovery, Security, Tracker-SDK) carry the Seventh Law inheritance pointer.

Mirror status

- Submodule pin lava-pin/2026-04-30-seventh-law-anchor pushed to GitHub
  - GitLab for all 13 affected submodules; per-mirror SHA convergence verified via `git ls-remote` per Sixth Law clause 6.C.

Lava-API-Go-2.0.6-2006 — 2026-04-29

Critical bugfix release. **Upgrade strongly recommended** for any 2.0.x deployment — every prior 2.0.x build had at least one of the four root causes below silently breaking authenticated endpoints.

Fixed

- **SP-3.5 — login 502 (three independent root causes in `internal/rutracker.Client`):**
  1. **IPv6 silent drop on Cloudflare's rutracker edge.** Go's `net.Dialer` preferred AAAA records; TLS handshake completed; request body uploaded; response was silently dropped. Fixed by `Transport.DialContext` rewriting `tcp` / `tcp6` → `tcp4` for the rutracker upstream client only.
  2. **Default redirect-following discarded the `bb_session` cookie.** Login response is `HTTP 302 + Location:/forum/index.php + Set-Cookie:bb_session=…`; the auth token is on the 302, not on `/index.php`. Default `http.Client.CheckRedirect` followed the 302 silently and the scraper saw the unauthenticated login form. Fixed by `CheckRedirect = http.ErrUseLastResponse`.
  3. **`charset.NewReader` on an empty body returned EOF.** The 302 carries `content-type: text/html; charset=cp1251` AND a zero-length body; first Read returned EOF; auth headers we needed were never inspected. Fixed by reading raw bytes first and short-circuiting on `len==0`.
- **SP-3.5b — search/favorites/etc. all returning empty for valid sessions.** `auth.UpstreamCookie` unconditionally prepended `bb_session=` to the `Auth-Token` header value; the Android client (and the legacy Ktor proxy) store the **raw upstream Set-Cookie line** at login, so the upstream request landed with `Cookie: bb_session=bb_session=…` — a doubly-prefixed cookie that rutracker parsed as anonymous. Fixed by forwarding tokens that already contain `=` verbatim.

Diagnostics

- `internal/handlers/login.go` now logs the raw scraper error (err.Error() only — credentials are never in err) so a future 502 is debuggable from `podman logs` alone.

Tests (Sixth Law)

- `TestNewClient_TransportForcesIPv4` — pins the IPv4 rewrite.
- `TestNewClient_DoesNotFollowRedirects` — pins `CheckRedirect = ErrUseLastResponse`.
- `TestUpstreamCookieForwardsCookieLineVerbatim` — pins the verbatim-forward branch with the real-world Set-Cookie shape.
- `TestUpstreamCookie_TokenWithEqualsForwardsVerbatim` — defensive guard that any `name=value` pair forwards as-is.

Each test is a Sixth-Law Challenge with a documented MUTATION rehearsal in the test KDoc.

Verified

- Operator's own credentials, real LAN, real device:
  - `POST /login → 200 + Success`.
  - `GET /search?query=ps4 → {"page":1,"pages":10,"torrents":[… 50 hits…]}` (first hit "Eternights").
- Pretag-verify (Sixth Law clause 5 mechanical gate): all 5 black-box probes green.

Lava-Android-1.1.3-1013 — 2026-04-29

Real-device verified on Samsung Galaxy S23 Ultra (SM-S918B / Android 16). This release fixes every issue surfaced by the operator's real-device testing on 2026-04-29 against the lava-api-go LAN service.

Fixed

- **SP-3.4 — mDNS service-type cross-match.** The `_lava._tcp` listener was cross-matching `_lava-api._tcp` services because `"lava-api".contains("lava")` is true. A discovered lava-api-go service ended up classified as the legacy Ktor proxy (`Endpoint.Mirror`), routing to the wrong port (8080) instead of the Go API's port (8443). Fixed by replacing the substring filter with strict prefix-with-dot matching (`matchesServiceType`).

- **SP-3.3 — Connections list cleanup, port-aware reachability, route-clean LAN Mirror:**
  - Database migration v5→v6 deletes legacy `type='Proxy'` rows (collapses the duplicate "Main" entry) and `Mirror` rows whose host contains `:` (legacy `ip:port` shape).
  - `ConnectionService.isReachable` is now Endpoint-aware: TCP probes the exact host:port the network layer would actually open per variant.
  - `NetworkApiRepositoryImpl.proxyApi` parses `host:port` out of `Mirror.host` instead of feeding it through Ktor's URLBuilder as a hostname; LAN Mirror without an explicit port defaults to 8080.
  - Discovery strips the embedded port at conversion time so persisted `Mirror` rows are bare-host shaped.
- **SP-3.2 — `Endpoint.Proxy` removed; Unauthorized search UX:**
  - Removed `Endpoint.Proxy` from the model entirely (the public lava-app.tech instance was retired). Pre-existing rows are migrated forward to `Endpoint.Rutracker` on read.
  - Search shows a "Login required" empty-state with a Login button when not signed in (no more misleading "Nothing found").
- **SP-3.1 — LAN HTTPS without manual cert install.** A dedicated permissive-TLS `OkHttpClient` (`@Named("lan")`) accepts any LAN-side server cert, used **only** for `Endpoint.GoApi` and LAN `Endpoint.Mirror`. The strict default client is unchanged for public Internet endpoints. The user mandate — "must work without manual installation" — is satisfied.

Changed

- `Endpoint.GoApi` now renders as **"Lava API"** in the Connections list (was "Mirror"), so the operator can distinguish a discovered Go service from a manually-configured rutracker mirror at a glance.

Tests (Sixth Law)

- Killed a 2h22m gradle test hang in `:core:domain:testDebugUnitTest` caused by 4 interlocking Third-Law bluff fakes (TestDispatchers, TestEndpointsRepository, TestLocalNetworkDiscoveryService, MainDispatcherRule).
- Added 25+ Sixth-Law Challenge tests across `:core:data`, `:core:domain`, `feature:connection`, `feature:menu`, `feature:search_result`. Each carries a documented MUTATION falsifiability rehearsal.

Compatibility

- Tested against `lava-api-go 2.0.6` (current API release).

- Also works against the legacy Ktor proxy and rutracker direct.

Lava-API-Go-2.0.5-2005 — 2026-04-29

Superseded by 2.0.6. Login fix (SP-3.5 root causes 1+2+3) shipped here; the search/favorites empty-results fix (SP-3.5b) landed in 2.0.6.

Lava-Android-1.1.2-1012 — 2026-04-29

Superseded by 1.1.3. Issue-1/2/3 SP-3.3 fixes shipped here; the SP-3.4 mDNS cross-match fix landed in 1.1.3.

Lava-API-Go-2.0.4-2004 — 2026-04-29

Container build hardening:

- `start.sh` and `build_and_release.sh` now export `BUILDAH_FORMAT=docker` so Podman builds Docker-format images that persist `HEALTHCHECK` directives.
- `build_and_release.sh` always rebuilds the `:dev` image with `--format=docker` before saving, so the saved image tarball never carries a stale OCI-format build.

Lava-API-Go-2.0.2-2002 — 2026-04-29

Sixth Law inheritance docs added across all `vasic-digital` submodules.

Lava-API-Go-2.0.0..2.0.2 — 2026-04-28..29

SP-2 — initial Go service migration. Cross-backend parity with the Ktor proxy verified (8/8 fixtures), k6 load tests green, real Postgres in podman, real HTTP/3 client. See `docs/superpowers/specs/2026-04-28-sp2-go-api-migration-design.md` and `docs/superpowers/plans/2026-04-28-sp2-go-api-migration.md` for the full design.

Lava-Android-1.1.0-1010 — 2026-04-29

SP-3 — Android dual-backend support: discover and route to lava-api-go alongside the legacy proxy.

Earlier history

See `git log --oneline --decorate` for the full history before the SP-2/SP-3 series; the changelog above starts at the point where the Sixth Law was instituted (2026-04-28).
