

What we now is the following to incorporate: for start fetch and pull the latest version of constitution and all other Submodules. make sure we are following all mandatory rules and constraints and that we are not ignoring or violating any of them! then, incorporate all supported types of the tests which will for every supported provider we have perform onboarding, perform various searches for only these particular provider being tested, then surf through the results and validate and verify the content. we MUST confirm that valid download options are accessible and working - download link (valid and not broken), access to torrent file download (really downloads the torrent file which is nonempty and valid) or gives us magnet link which is 100% valid! We must through newly added tests replace need for manual testing by real human! we must write down besides this main scenario all use cases which real human user would do, then test all these cases, all cases around it, all variations and edge cases! if we have not incorporated yet HelixQA we must do it now: <https://github.com/HelixDevelopment/HelixQA> (git@github.com:HelixDevelopment/helixqa.git). HelixQA is fully under our control like all other Submodules from vasic-digital and HelixDevelopment organizations! We MUST create comprehensive test suites and banks of tests which HelixQA will execute and confirm that all features we have been mentioning are fully functional! Besides test banks HelixQA MUST perform full autonomous QA sessions related to each provider, browsing searching, obtaining the download access! If anything we want to achieve is missing, or we still do not have needed functionality you do it, we MUST extend all our Submodules or main project so the means are there! All tests MUST produce real results! There cannot be any false results or bluff of any kind! Every test we execute with success MUST produce real rock-solid physical proofs of all functionalities, fixes, changes or improvements really working as expected! Everything MUST produce the real evidence! Make sure that we follow code review agents rules / constraints in our work flow(s) defined in our root constitution Submodule! Make sure we provide bridge to HelixQA (which MUST be already implemented in it) from you (Claude Code) to provide all LLM and Vision and other model needs to it! You will then be able to track and monitor in real time EVERYTHING that HelixQA is doing, to apply additional improvements, fixes, fill the gaps or fix any detected shortcoming in HelixQA itself and the main project!

We are providing now credentials you can add into the .env file to access various trackers:

<redacted — RuTracker creds live only in gitignored .env per §6.H>
<redacted — RuTor creds live only in gitignored .env per §6.H> <redacted —
IPTorrents creds live only in gitignored .env per §6.H> <redacted —
NNMClub creds live only in gitignored .env per §6.H>

Make sure none of them leaks through Git versioning or through the logs!
Use credentials for all 4 providers / trackers! For the ones that we still do not support, incorporate fully those providers! Do in-depth analysis and research of Jackett (<https://github.com/Jackett/Jackett>, git repo: git@github.com:Jackett/Jackett.git). There are already supported various trackers (providers)! It would be ideal if we can add Jackett as Submodule and then directly to create Providers (provider / tracker implementations) which will directly reference all this codebase so we do not have to port it! If that is not possible, port all supported providers / trackers from Jackett and make sure all of them are fully covered with comprehensive tests, Challenges and HelixQA test banks and full autonomous sessions! Do as much as needed deep web research to achieve all described goals! Feel free to incorporate additional 3rd party libraries and solutions and new approaches we could use to properly test our features! We MUST make sure that EVERYTHING is fully decoupled, abstractions, all implementations, so new implementation / flavors and strategies are easy to implement! Especially all providers / trackers! Another thing that MUST be kept in mind is that in near future we MUST BE able to add new providers by installing Android extension APKs or use any relevant technology to achieve this! All providers MAY BE hosted / published to Google Play Store or other markets under same or different development accounts and created by the same or community driven teams! For all this we MUST maximally extend all documentation, user guides and manuals, architectural materials, all diagrams and schemes, SQL definitions and all other materials! Make sure we regularly commit and push all Submodules and main repo to all upstreams! Aim for maximal tests coverage by all supported test types of all our codebase - every single line! Keep us updated about the progress and all relevant events!
