

run-genymotion-challenges.sh

Genymotion Challenge runner (§6.AH VM path).

Script: `scripts/run-genymotion-challenges.sh`

What it does

Genymotion runs Android inside a VM, so it satisfies §6.AH ("virtual devices / emulators MUST run in Containers or VMs — never host-direct").
THIN GLUE:

1. Device detection + boot/stop is delegated to the Containers submodule's `cmd/genymotion` CLI (the §6.AG "driven by the Containers submodule" requirement) — never a live/physical ADB device.
2. The Challenge install + instrumentation runs through Gradle's `connectedDebugAndroidTest` against the resolved Genymotion adb serial.
3. Records the per-Challenge outcome as §6.I/§6.AE attestation evidence.

This is the DEBUG-variant on-VM Challenge runner; the RELEASE variant cold-start is covered by `scripts/run-release-canary.sh` (there is no `connectedReleaseAndroidTest` — the app's `testBuildType` is debug).

Usage

```
./scripts/run-genymotion-challenges.sh [--test-class  
lava.app.challenges.ChallengeNN] [--evidence-dir <dir>]
```

Constitutional bindings

§6.AH (VM emulator, never host-direct), §6.AG (Containers-driven device),
§6.AE (Challenge coverage), §6.I (per-AVD attestation), §6.U (no sudo).
