

scripts/run-challenge-matrix.sh

— User Guide

Last verified: 2026-05-16 (HelixQA Option 1 wiring landed — --include-helixqa flag added) **Inheritance:** HelixConstitution §11.4.18 + Lava §6.AE.6 + §6.X (Container-Submodule Emulator Wiring) + §6.I (Multi-Emulator Container Matrix)

Overview

Operator entry point for §6.AE gate-mode Challenge Test runs. Pre-bakes the §6.AE.2 minimum AVD matrix (API 28 / 30 / 34 / latest stable × phone + tablet) and delegates to submodules/containers/cmd/emulator-matrix --runner=containerized per §6.X.

Honest pre-flight

The script DETECTS the §6.X-debt darwin/arm64 host gap (no /dev/kvm available to podman containers; macOS HVF not exposed to podman) and, when detected, REFUSES to claim a successful gate run. Instead it:

1. Validates arguments + matrix minimum
2. Writes <evidence-dir>/host-preflight.json with the host-gap classification
3. Exits 2 (NOT 0) — gate-host ineligible

Per §6.J/§6.L: no false-pass; honest unblock report. Real gate runs require a Linux x86_64 + KVM host.

Usage

```
# Run ALL Challenges on the §6.AE.2 minimum matrix
bash scripts/run-challenge-matrix.sh
```

```
# Run a specific Challenge
bash scripts/run-challenge-matrix.sh \
    --test-class
        lava.app.challenges.Challenge01AppLaunchAndTrackerSelectionTest
```

```
# Add TV-class AVD (when feature touches TvActivity)
```

```

bash scripts/run-challenge-matrix.sh --add-tv

# Add foldable AVD
bash scripts/run-challenge-matrix.sh --add-foldable

# Override "latest stable" API level
bash scripts/run-challenge-matrix.sh --latest-api 36

# Skip APK rebuild
bash scripts/run-challenge-matrix.sh --no-build

# Override the matrix entirely with explicit AVDs (target EXISTING
  host AVDs).
# Use on a macOS host-direct+HVF run where the default CZ_API*
  images are not provisioned.
bash scripts/run-challenge-matrix.sh --avds
  "CZ_API35_Phone_Fresh:35:phone" --no-build

# ALSO invoke the 11 HelixQA Challenge scripts (Option 1 wiring)
bash scripts/run-challenge-matrix.sh --include-helixqa

```

Inputs

Arg	Description
--test-class <fqcn>	Specific Challenge to run (default: all under lava.app.challenges)
--evidence-dir <dir>	Output directory (default: dated under .lava-ci-evidence/)
--no-build	Skip the :app:assembleDebug step
--avds "<name:api:form[,...]>"	Replace the \$6.AE.2 default matrix entirely with an explicit comma-separated AVD list. Use to target existing host AVDs (e.g. CZ_API35_Phone_Fresh:35:phone on a macOS host-direct+HVF run where the default CZ_API* images are not provisioned). When set, --latest-api / --add-tv / --add-foldable are ignored. A sub-minimum list is a development-iteration run, not a \$6.AE.2-conformant gate matrix. NOTE: the Containers CLI still resolves each AVD's system image through tools/lava-containers/vm-images.json (--image-manifest); the manifest must contain a matching image id (e.g. android-35-phone) or the runner fails with no image with id.
--latest-api <N>	

Arg	Description
	Override the "latest stable" API level (default: 36; ignored when --avds is set)
--add-tv	Add a TV-class AVD to the matrix
--add-foldable	Add a foldable AVD
	ALSO invoke scripts/run-helixqa-challenges.sh (the 11 HelixQA Challenge scripts per Option 1 wiring). OFF by default so existing matrix runs are unaffected. HelixQA runs on the HOST BEFORE the AVD matrix → independent of §6.X-debt darwin/arm64 gate-host gap. HelixQA wrapper evidence lands at <evidence-dir>/helixqa/. Non-zero HelixQA exit promotes the final aggregate exit code (matrix exit dominates if both fail). See docs/scripts/run-helixqa-challenges.sh.md for full details.
--include-helixqa	

§6.AE.2 mandatory minimum matrix

```
CZ_API28_Phone:28:phone
CZ_API30_Phone:30:phone
CZ_API34_Phone:34:phone
CZ_API34_Tablet:34:tablet
CZ_API<latest>_Phone:<latest>:phone
```

Plus TV / foldable when explicitly requested by --add-tv / --add-foldable.

Sub-minimums are permitted for development iteration; the gate row's gating: true flag is only set when the full minimum is satisfied + every config dimension (theme/locale/density per §6.AE.2) is covered.

Outputs

- <evidence-dir>/host-preflight.json — host-gap classification (always written)
- <evidence-dir>/real-device-verification.{md,json} — per-AVD attestation rows (only on Linux x86_64 + KVM gate-host)
- <evidence-dir>/helixqa/helixqa-attestation.json + per-script logs — only when --include-helixqa is set

Exit codes

Code	Meaning
0	Matrix completed; all AVDs passed
1	At least one AVD failed boot OR at least one test failed (real Containers CLI exit)
2	Gate-host ineligible (darwin/arm64 OR no KVM); honest unblock-needed report written

Cross-references

- `submodules/containers/cmd/emulator-matrix` (the underlying runner)
