

scripts/autonomous-qa/release-coldstart-canary.sh

RELEASE-variant R8 cold-start canary (§6.AA Two-Stage Distribute + §6.Z.4 cold-start mandate).

Why it exists

The project has **no** `testBuildType=release`, so the instrumentation keystone (Challenge70 / Challenge00CrashSurvivalTest) can only run against the DEBUG APK. The R8-minified **release** APK therefore has no on-device instrumentation coverage — yet the §6.Z forensic anchor (Lava-Android-1.2.19-1039) was a **release-only** R8 crash (painterResource on a <layer-list> at MainActivity.setContent) that the debug build did NOT reproduce. §6.AA clause 4 names this "R8 / minification surprise" class as the load-bearing reason for the two-stage distribute.

This canary is the release-variant equivalent of the C00 cold-start gate.

What it does

1. Boots ONE containerized emulator via `lib-emulator.sh` (§6.AH — never host-direct).
2. Fresh-installs the RELEASE APK (`digital.vasic.lava.client`, no `.dev`).
3. `pm clear` + cold-launches it (`monkey ... LAUNCHER 1`).
4. Waits, then captures `logcat` + a screenshot.
5. Emits a `verdict.json`. **PASS requires ALL THREE** (a cold-start crash breaks all three, so PASS cannot be bluffed by a crashed app):
 - no FATAL EXCEPTION for the package in `logcat`,
 - the app process is ALIVE (`pidof`),
 - the app's activity is the TOP resumed activity (`dumpsys activity`).

Usage

```
# after ./gradlew :app:assembleRelease
scripts/autonomous-qa/release-coldstart-canary.sh \
  [--apk app/build/outputs/apk/release/app-release.apk] \
  [--evidence-dir .lava-ci-evidence/1079-release-coldstart]
```

Exit: 0 PASS · 1 FAIL (crash / not-foregrounded) · 2 setup error
(missing APK or emulator boot failure).

Evidence

--evidence-dir/verdict.json (curated, tracked) records the variant, package, APK sha256, fatal count, pid, top activity, and verdict. raw/ (gitignored) holds the full logcat + screenshot. The verdict.json is the release-stage \$6.Z evidence referenced by the distribute-changelog <version>-test-evidence file.
